

Background-Limited Infrared-- Submillimeter Spectroscopy (BLISS)

Matt Bradford
June 10, 2004

Thanks to the ISM in galaxies, half the power in the universe emerges in the far-IR

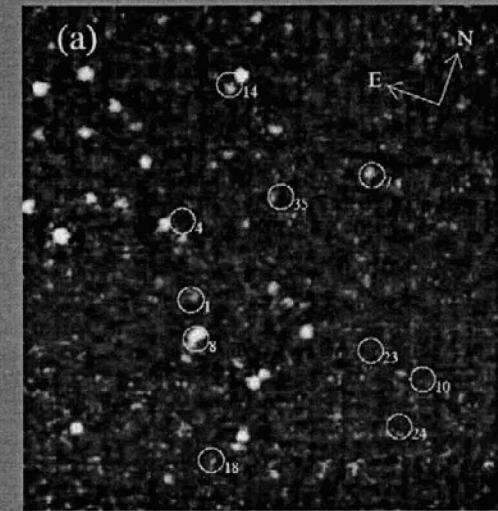

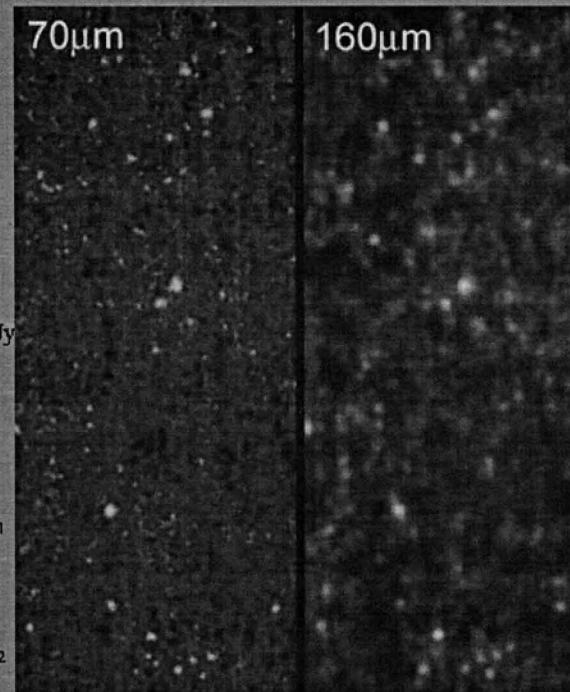

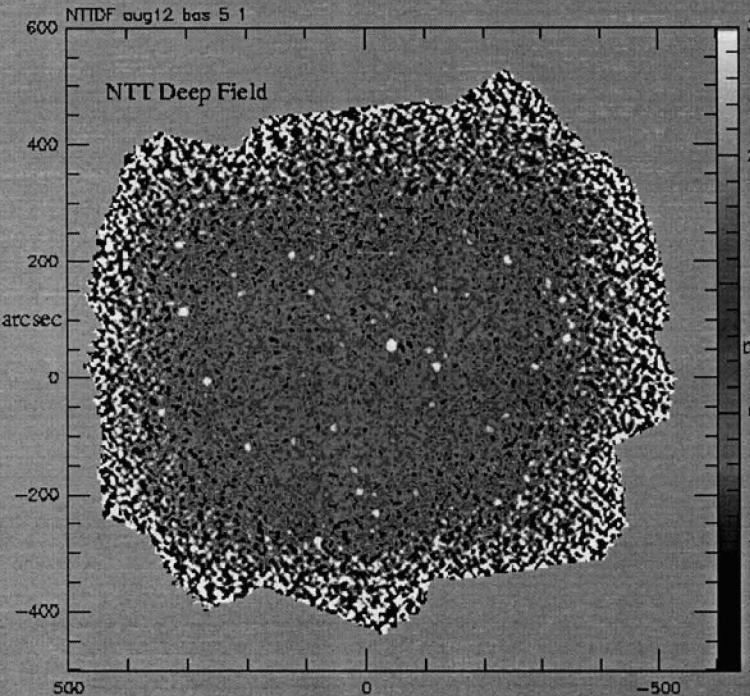

- Dust reprocesses star formation and accretion luminosity into the far-IR
- Dust hides luminosity sources at their short wavelengths
- Dust extinction is typically associated with the dense ISM.

→ Mid-IR through mm wavelengths is the way to study the dense ISM

S. Michael Fall, IAU V. 204, 2001

Far-IR background being resolved into galaxies

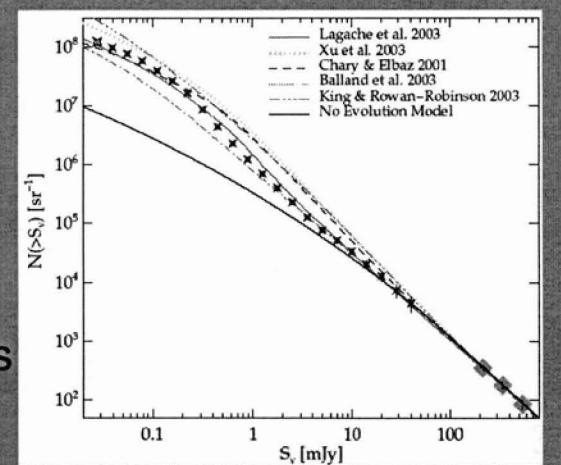

MAMBO / IRAM 30 m
1.3 mm 60 hours, 40 sources

Bertoldi et al. (2000);
Carilli et al. (2001c, 2002b);

MIPS 24 μm counts
Bulk of background
Papovich et al. 2004

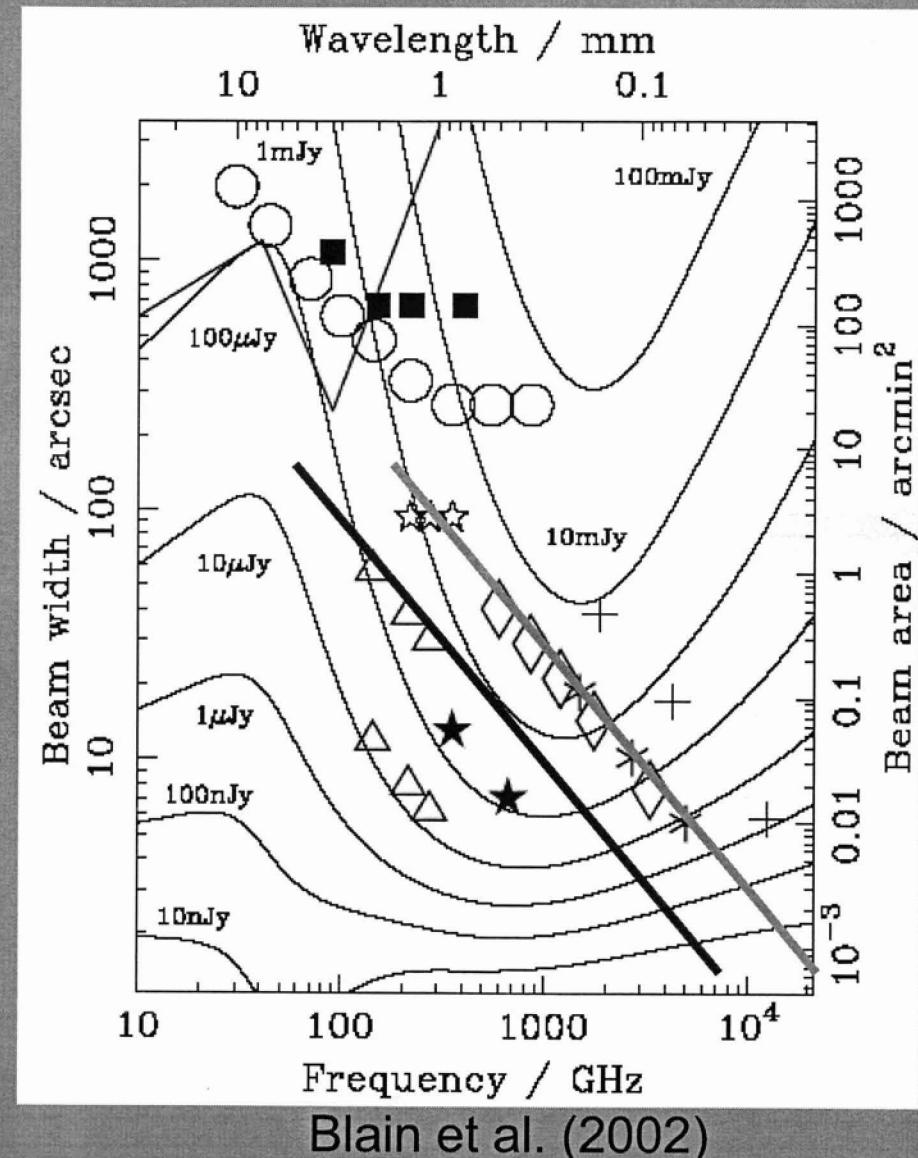

Larger telescopes will resolve the bulk of the background

TABLE 3
POTENTIAL RESOLUTION OF THE COSMIC INFRARED BACKGROUND

	$24 \mu\text{m}^a$	$70 \mu\text{m}^a$	$160 \mu\text{m}^a$
<i>Spitzer</i>	74%	59%	18%
Herschel ^b /SPICA	98%	93%	58%
JWST ^b	99%	—	—
SAFIR	100%	99%	94%

NOTE. — (a) Using the CIB value from Lagache et al. (2004) and using the limiting flux using the SDC limit and assuming confusion-limited surveys. (b) This hypothesis might not be valid for Herschel and JWST.

Dole et al. (2004)

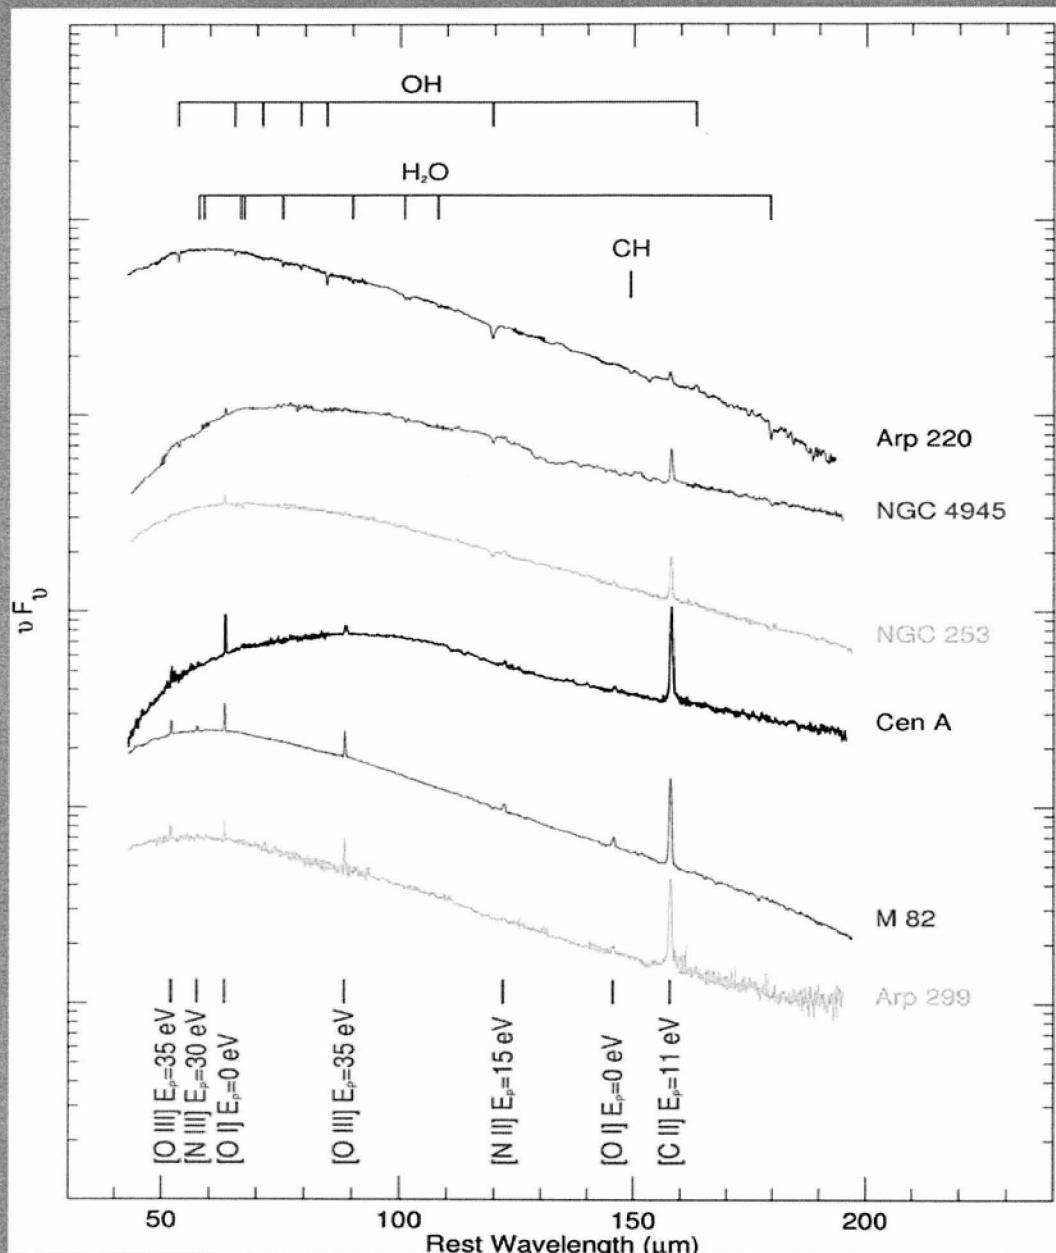

Submillimeter-radio selected sources are luminous galaxies at $1 < z < 4$

Chapman et al. (2003)

Spectral Features for $\lambda_{\text{rest}} = 10 - 500 \mu\text{m}$

- Suite of lines provides redshift template independent of optical follow-up.
- Fine structure lines probe ionized and neutral atomic gas
 - HII region densities
 - Atomic gas pressures
 - UV field strength and hardness
 - Starburst / AGN discriminator
 - Stellar mass function
- Rotational transitions cool molecular gas
 - Measures temperature, density and total mass.
- Lowest H₂ rotational lines cool primordial gas forming first stars
 - 12-28 mm at $z \sim 10-50$

J. Fischer et al. 1999

Reminder: Dense ISM mass budget

More than 99% is gas

ionized	~10%
neutral atomic	~50%
UV-illuminated molecular	~10%
UV-shielded molecular	~50%

Top 3 are the interesting phases, not traced with mm-wave probes.

and mid to far-IR is the only way to overcome extinction.

High frequency spectral lines probe the interaction between stars / AGN and ISM

Table 2. Far-Infrared Spectral Features

Species	Wavelength [μm]	f (M82)	f (Arp220)	Diagnostic Utility
<i>Ionized Gas Fine Structure Lines</i>				
O IV	25.9, 54.9			Primarily AGN
S IV	10.5	2.1 (-5)		
Ne II	12.3	1.2 (-3)	7.5 (-5)	Probes gas density and
Ne III	15.6, 36.0	2.05 (-4)		UV field hardness in
S III	18.7, 33.5	1.0 (-3)	7.3 (-5)	star formation HII
Ar III	21.83	9.1 (-6)		regions.
O III	51.8, 88.4	1.3 (-3)		
N III	57.3	4.2 (-4)		
N II	122, 205	2.1 (-4)		Diffuse HII regions
<i>Neutral Gas Fine Structure Lines</i>				
Si II	34.8	1.1 (-3)	7.7 (-5)	Density and temperature probes
O I	63.1, 145	2.2 (-3)	6.8 (-5) (abs)	of photodissociated-neutral
C II	158	1.6 (-3)	1.3 (-4)	gas interface between HII
C I	370	6.2 (-6)	1.2 (-5)	regions and molecular clouds.
<i>Molecular Lines</i>				
H ₂	9.66, 12.3, 17.0, 28.2	2 (-5)	3 (-5)	Coolants of first collapse
CH	149		4 (-5)	Ground state absorbtion:
OH	34.6, 53.3, 79.1, 119	2 (-6)	2 (-4) (abs)	gives column and abundance.
OH	98.7, 163		5 (-5)	Emission: gas coolants, constrain
H ₂ O	73.5, 90, 101, 107, 180		5 (-5)	temperature, density of warm
CO	325, 372, 434, 520	3 (-6)	1 (-5)	(50K < T < 500 K) mol. gas

Note: f(M82) and f(Arp220) are the fraction of the total IR luminosity that emerges in each line. Observations are from ISO (C99, G98, FS01, F99)

Even low-metallicity starbursts emit most of their flux in the IR

In this case, the mid-IR-> 20 microns.

SBS0335-052

Optical $Z/Z_o \sim 1/41$

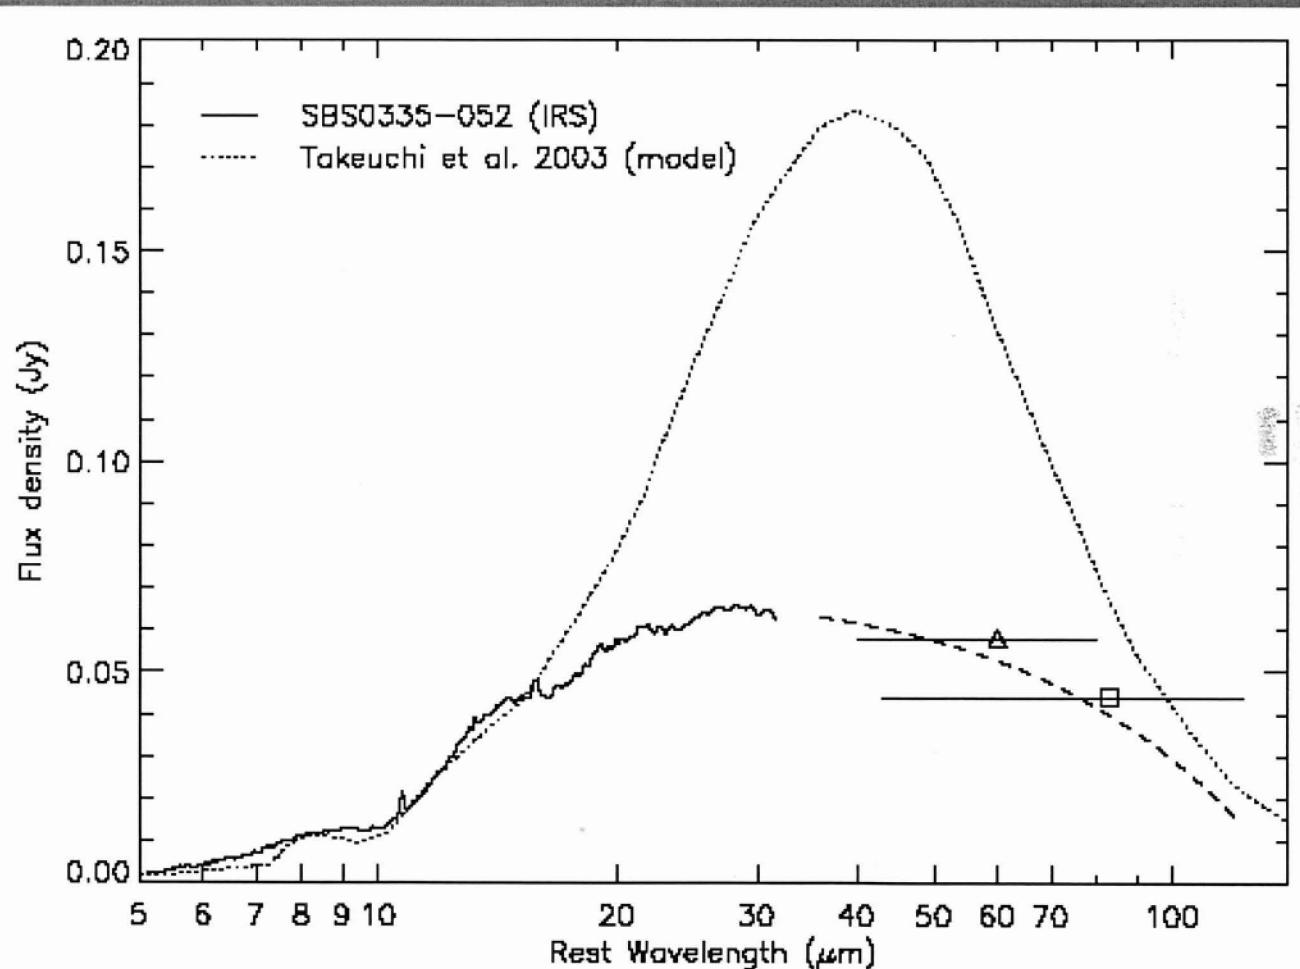

SiIV, NIII fine structure

lines imply:

$\rightarrow T_{\text{eff}} > 40,000$ K

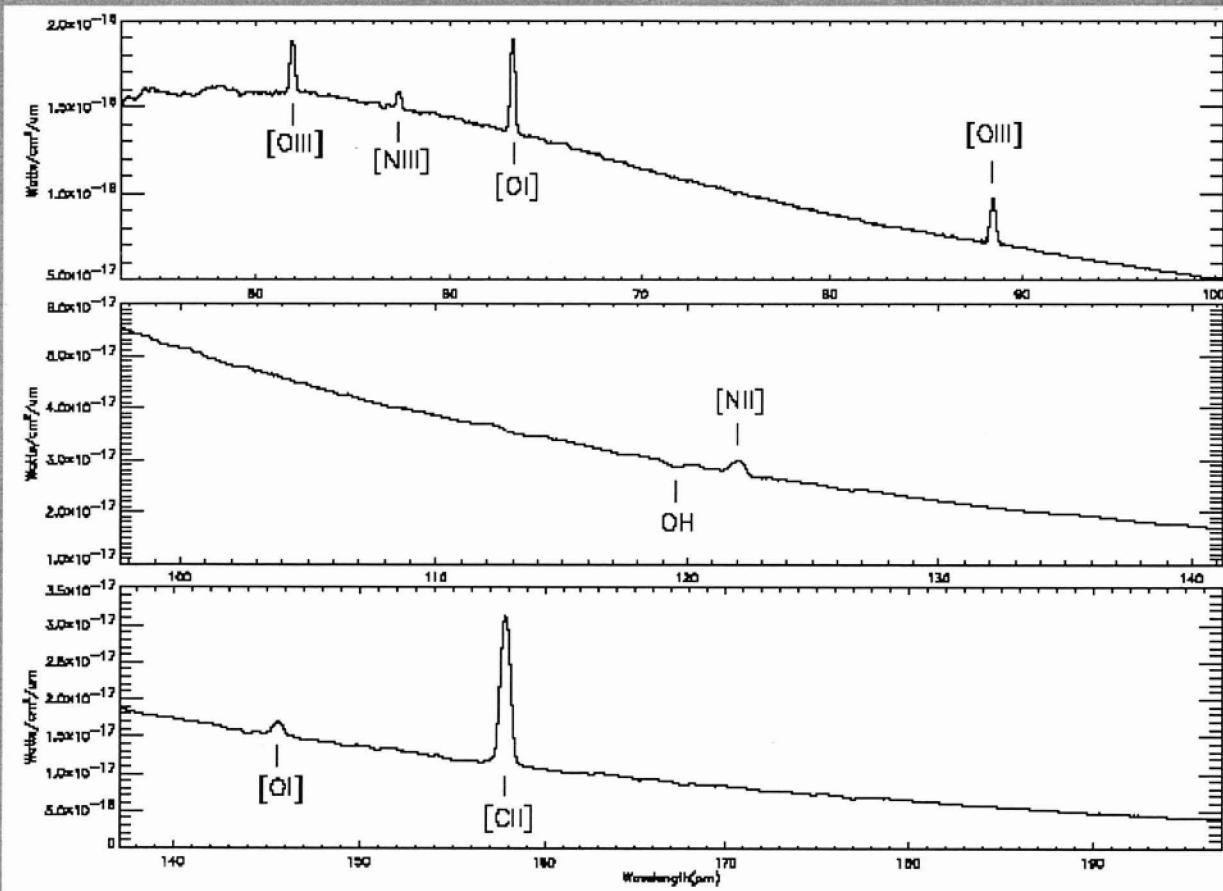

\rightarrow Ne, S abundance
higher than $Z_o/41$

IR-emitting region polluted
by WR winds, SN remnants

Houck et al. 2004

M82: An extragalactic case study for far-IR spectroscopy

ISO LWS Grating Spectrum:

7 fine slits, 1.0 arcsec

HII regions:
 $n_e \sim 250 \text{ cm}^{-3}$

PDRs:
 $n \sim 10^{3.3}$,
 $G_0 \sim 10^{2.8}$

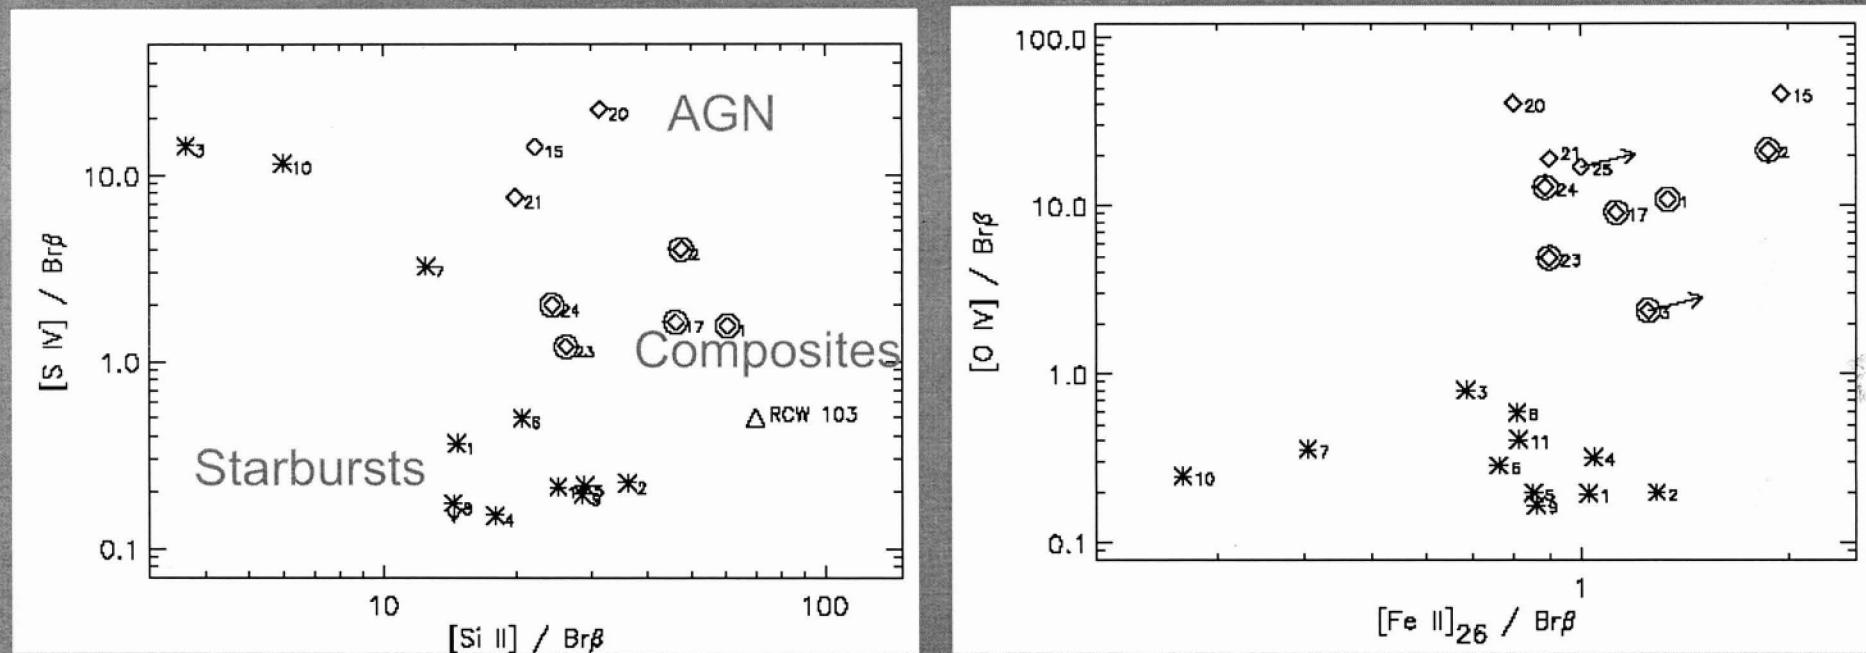

CII from PDRs (75%)
and HII regions (25%)

Model: 3.5 Myr starburst with
100 M_{sun} cutoff

Starburst mass $\sim 0.5\text{--}1.3 \times 10^9 \text{ M}_\odot$
 $\sim 1/2$ the total gas mass

Colbert, Malkan et al. 1998

Line ratios rapidly distinguish starburst from AGN luminosity source

Sturm et al. 2002 -- ISO SWS data

Far-IR / submm Molecular Gas Probes

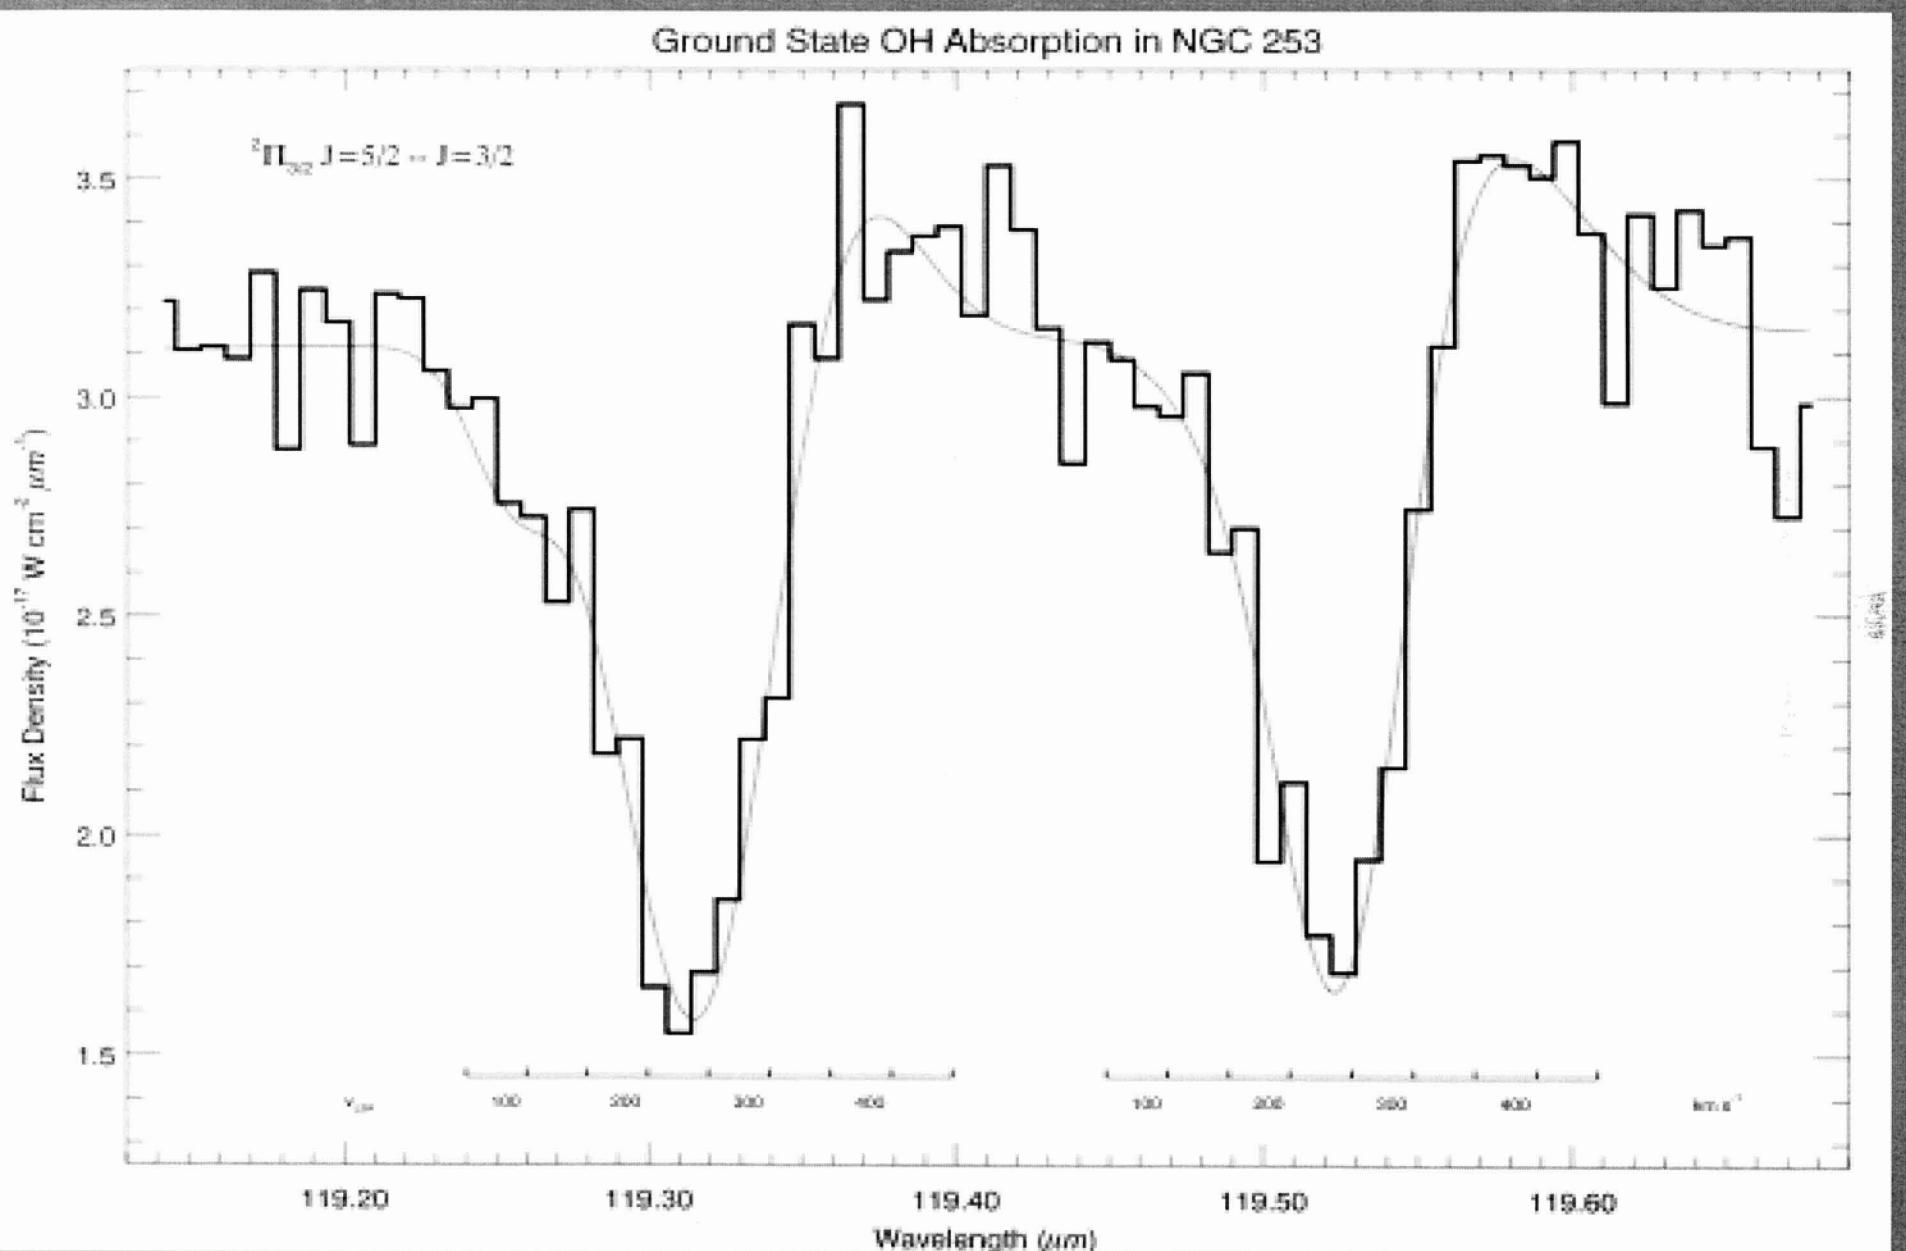

- Mid- and high-J lines of CO are required to accurately constrain molecular gas mass, temperature, and luminosity.
- A host of small molecules have their fundamental rotational transitions in the far-IR.

$$v_0 \sim 1 / (\text{Moment of Inertia})$$

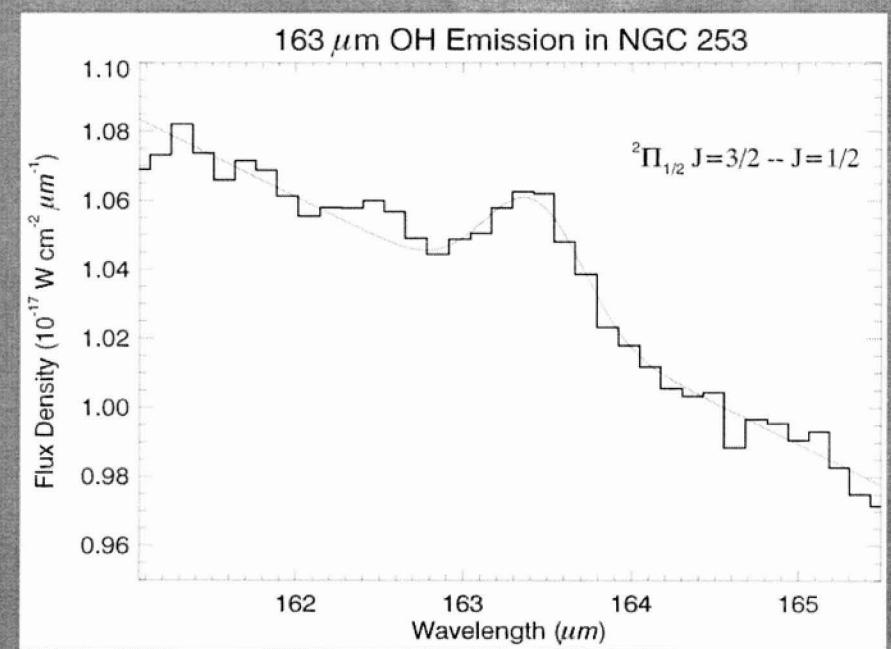

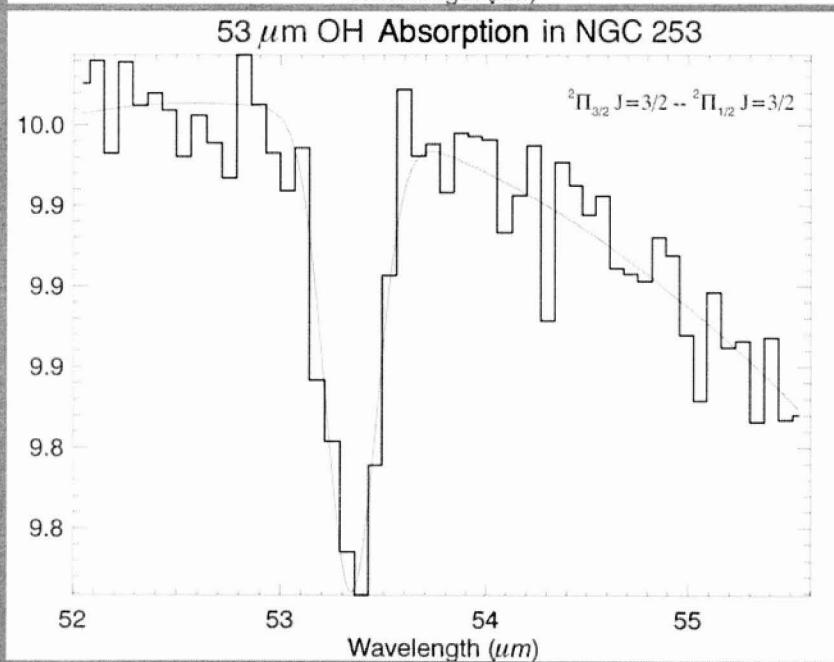

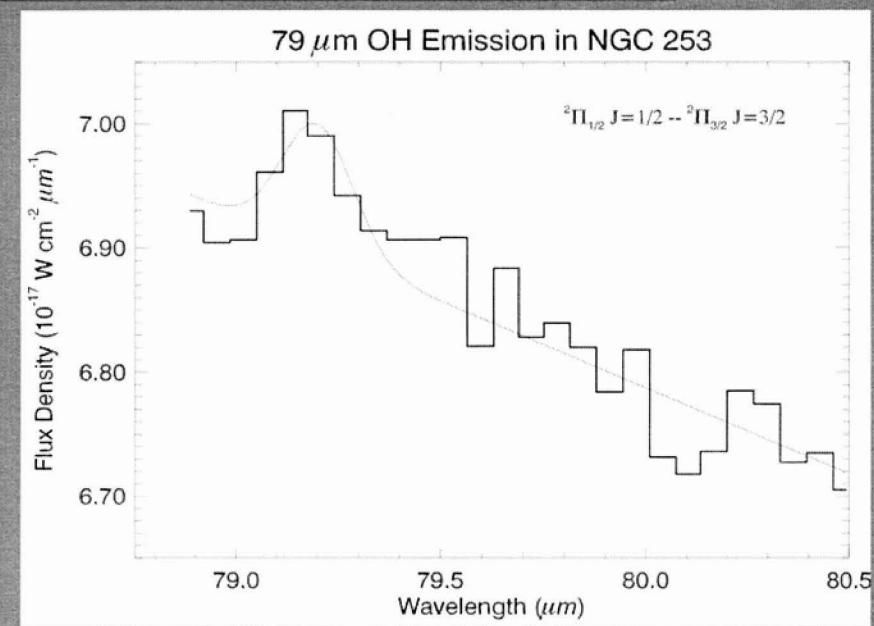

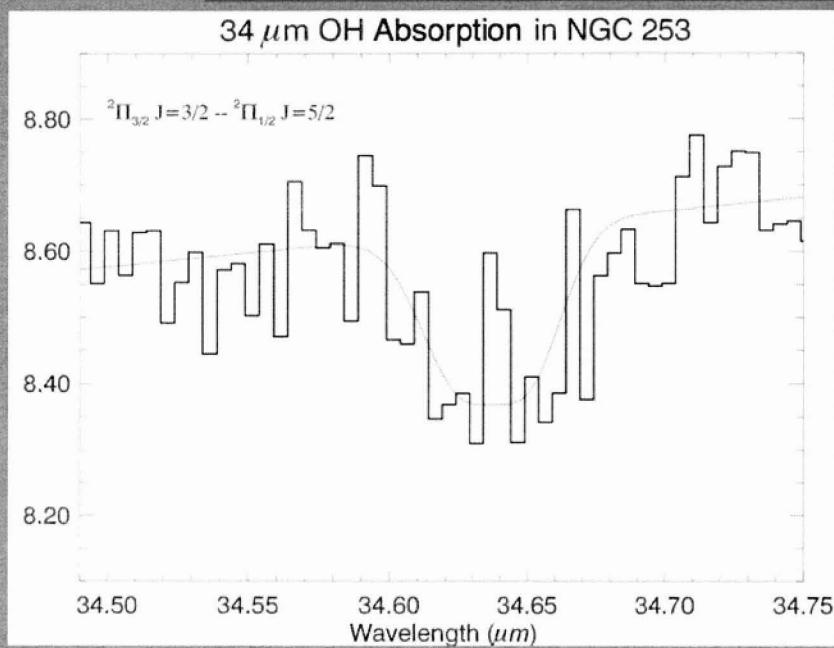

- Bright far-IR continuum can give absorption --> direct column density measure.
- Pumps Masers

Example of far-IR galaxy-scale molecular probes: OH in NGC 253

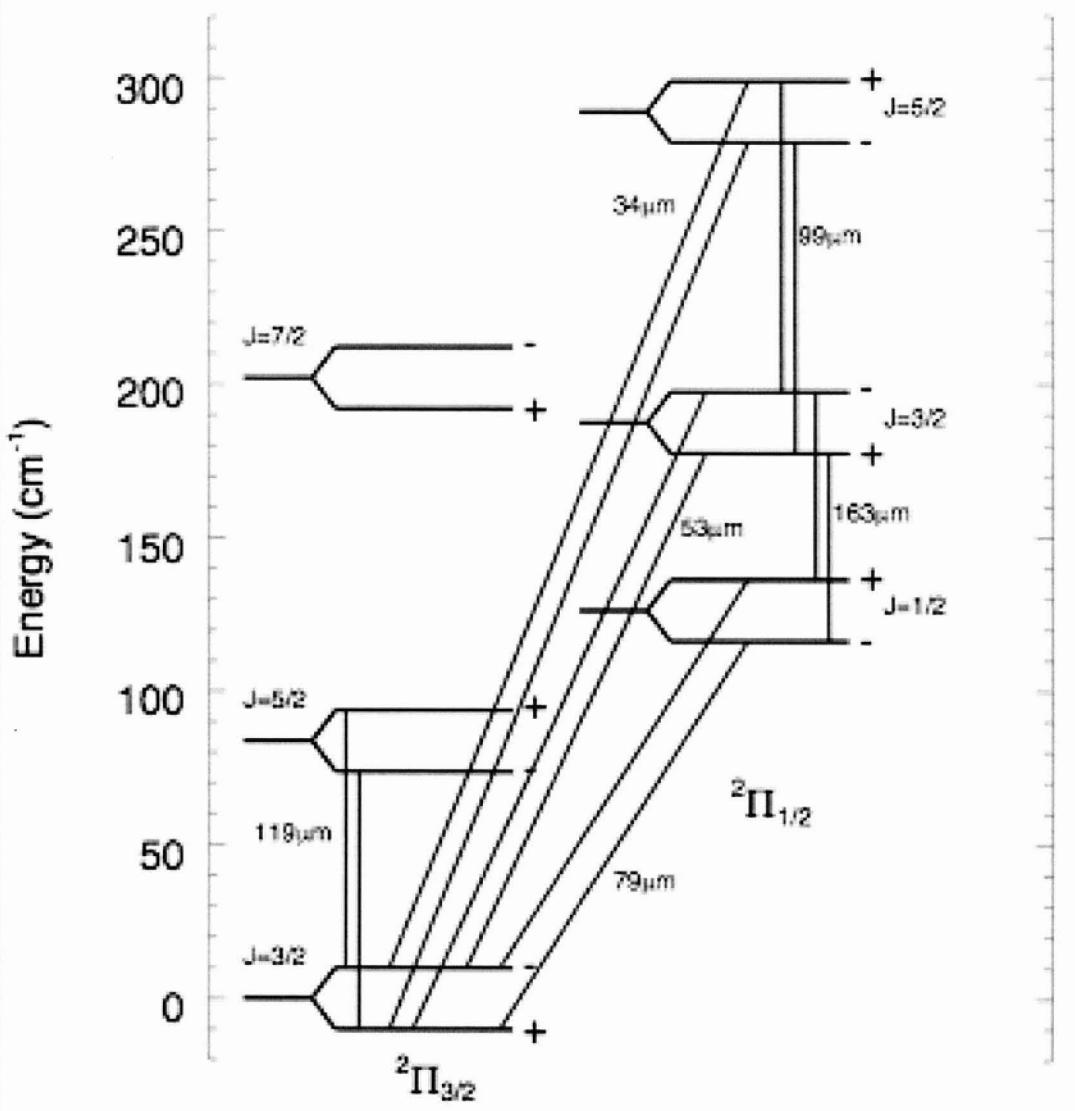

Example of far-IR galaxy-scale molecular probes: OH in NGC 253

Example of far-IR galaxy-scale molecular probes: OH in NGC 253

Lowest Rotational Energy Levels of OH

OH -- radiative rates are very fast, transitions not thermalized -- must account for radiative cascade.

$$\begin{aligned}34 \text{ } \mu\text{m} &\rightarrow \tau \sim 0.5 \\53 \text{ } \mu\text{m} &\rightarrow \tau \sim 0.12 \\119 \text{ } \mu\text{m} &\rightarrow \tau \sim 16\end{aligned}$$

Modeling with multiple transitions \rightarrow

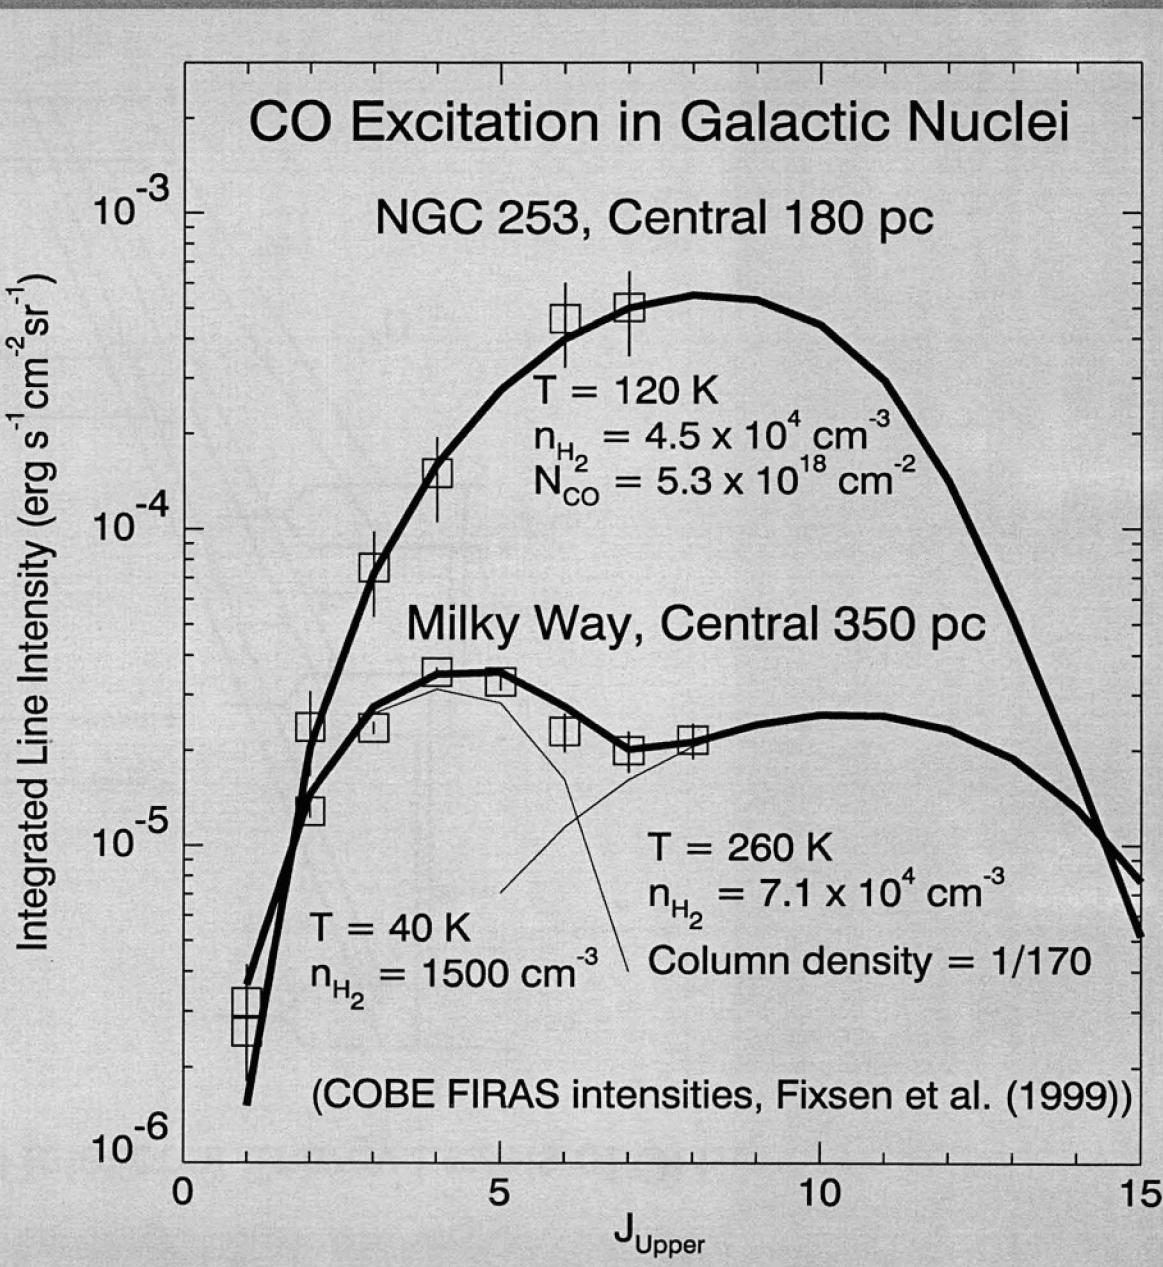

$$N_{\text{OH}} = 1.0 \times 10^{17} \text{ cm}^{-3}$$

$$X_{\text{OH}} = 1.4 \times 10^{-7}$$

Bradford et al. 1999

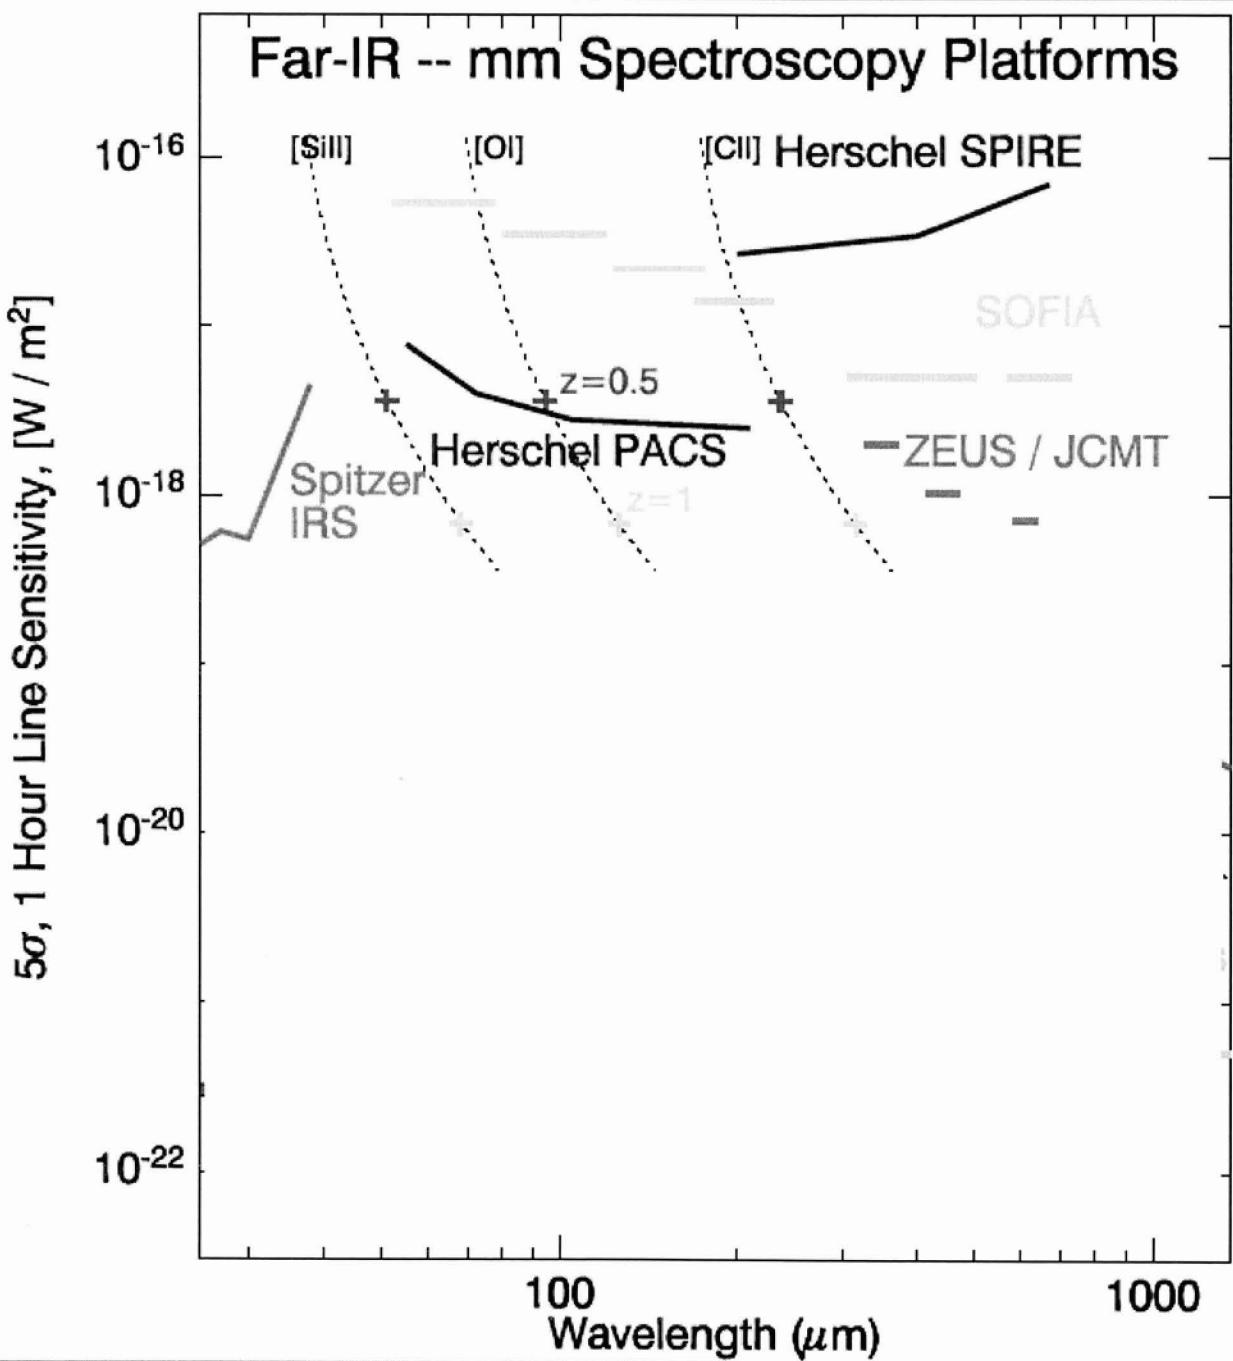

High-J CO lines: Astrophysics of the molecular gas

- LVG modeling: intensities → physical conditions
- Mid-J lines ($J > 4$) distinguish low excitation from high excitation gas

NGC 253:
Bulk of molecular gas heated to $T > 100 \text{ K}$ by cosmic rays, turbulence (SPIFI – JCMT)
Bradford et al '03

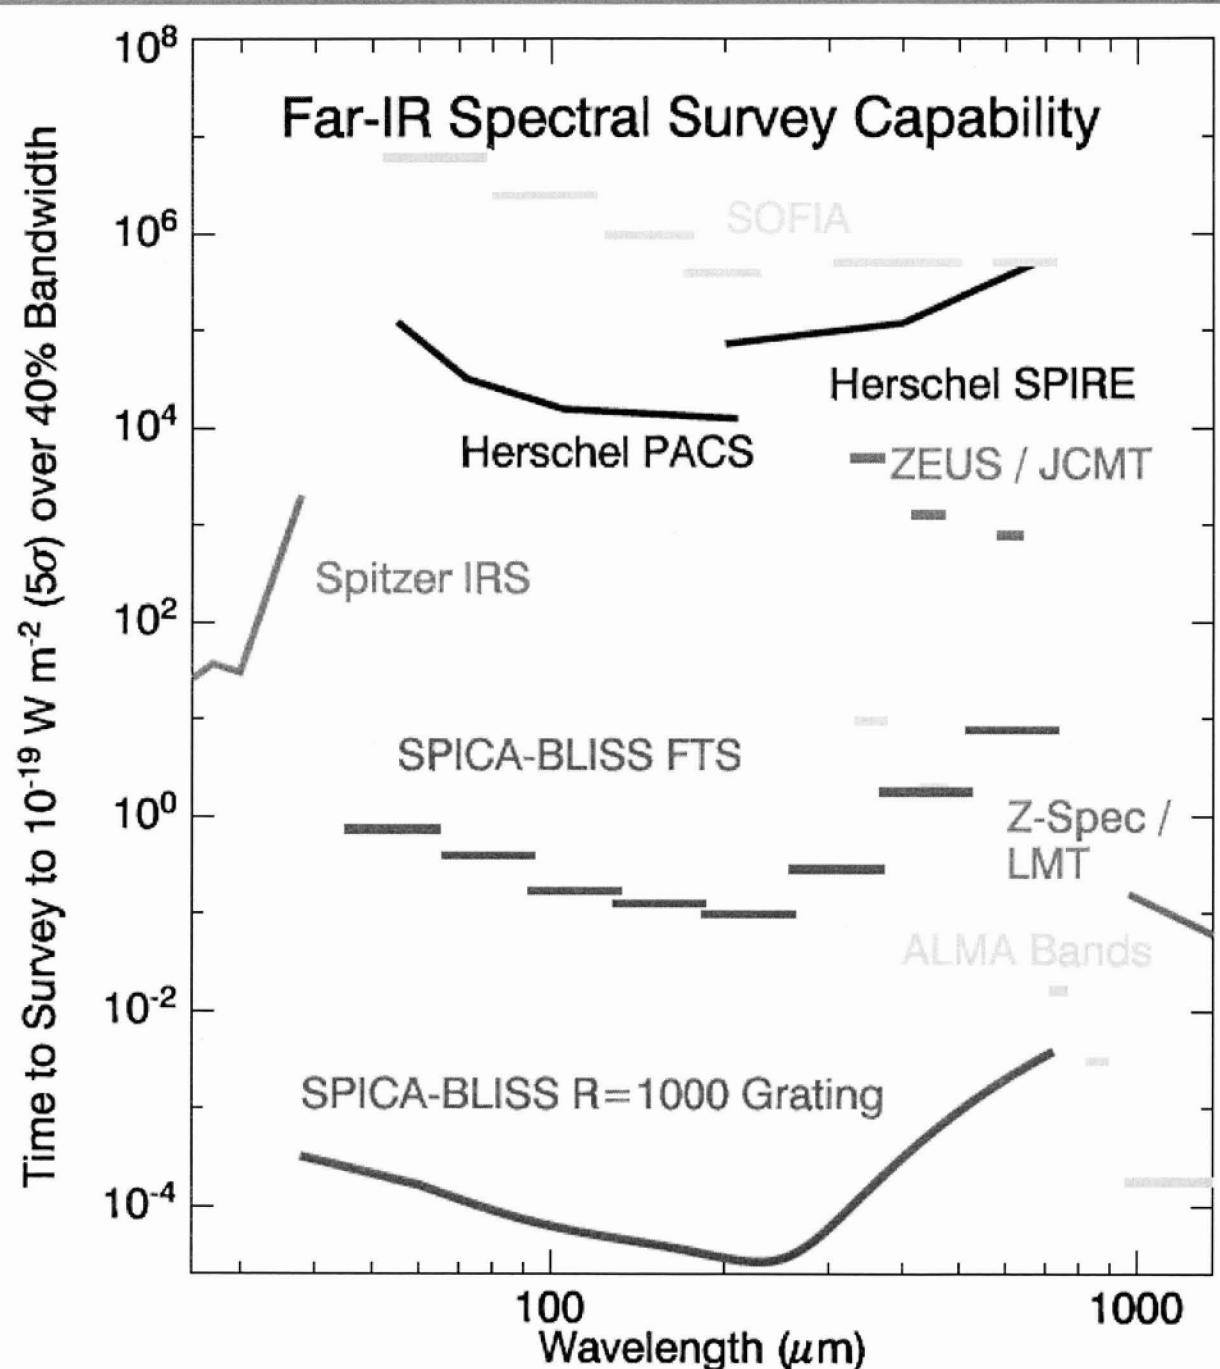

Milky Way:
Mostly cool gas with small warm component from star formation regions, CND

Huge advances are still possible in the far-IR with a cold space telescope.

Herschel, SOFIA and ground based platforms are limited by emission from warm telescopes.

Ultimate limitation is photon noise from the astrophysical backgrounds.

Capability increase
for broadband line
surveys is even
greater.

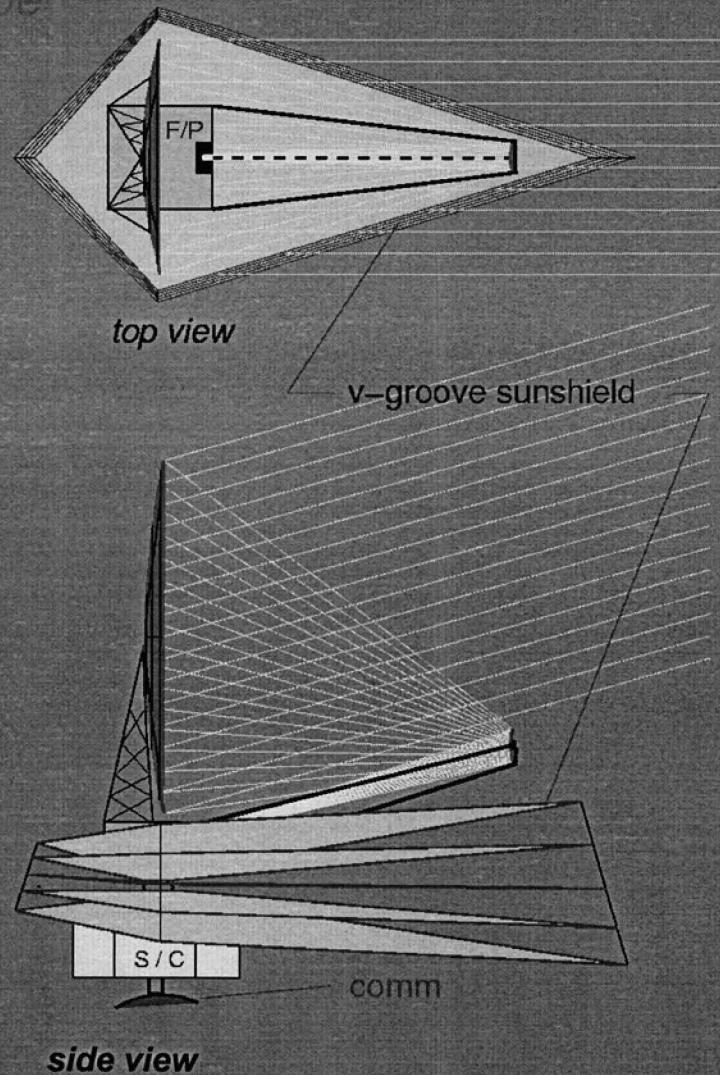

Most existing
spectrometers are
not well-suited to a
large instantaneous
bandwidth -- incur a
time (sensitivity)
penalty in obtaining a
complete spectrum.

*Note: Spitzer IRS is
notable exception.*

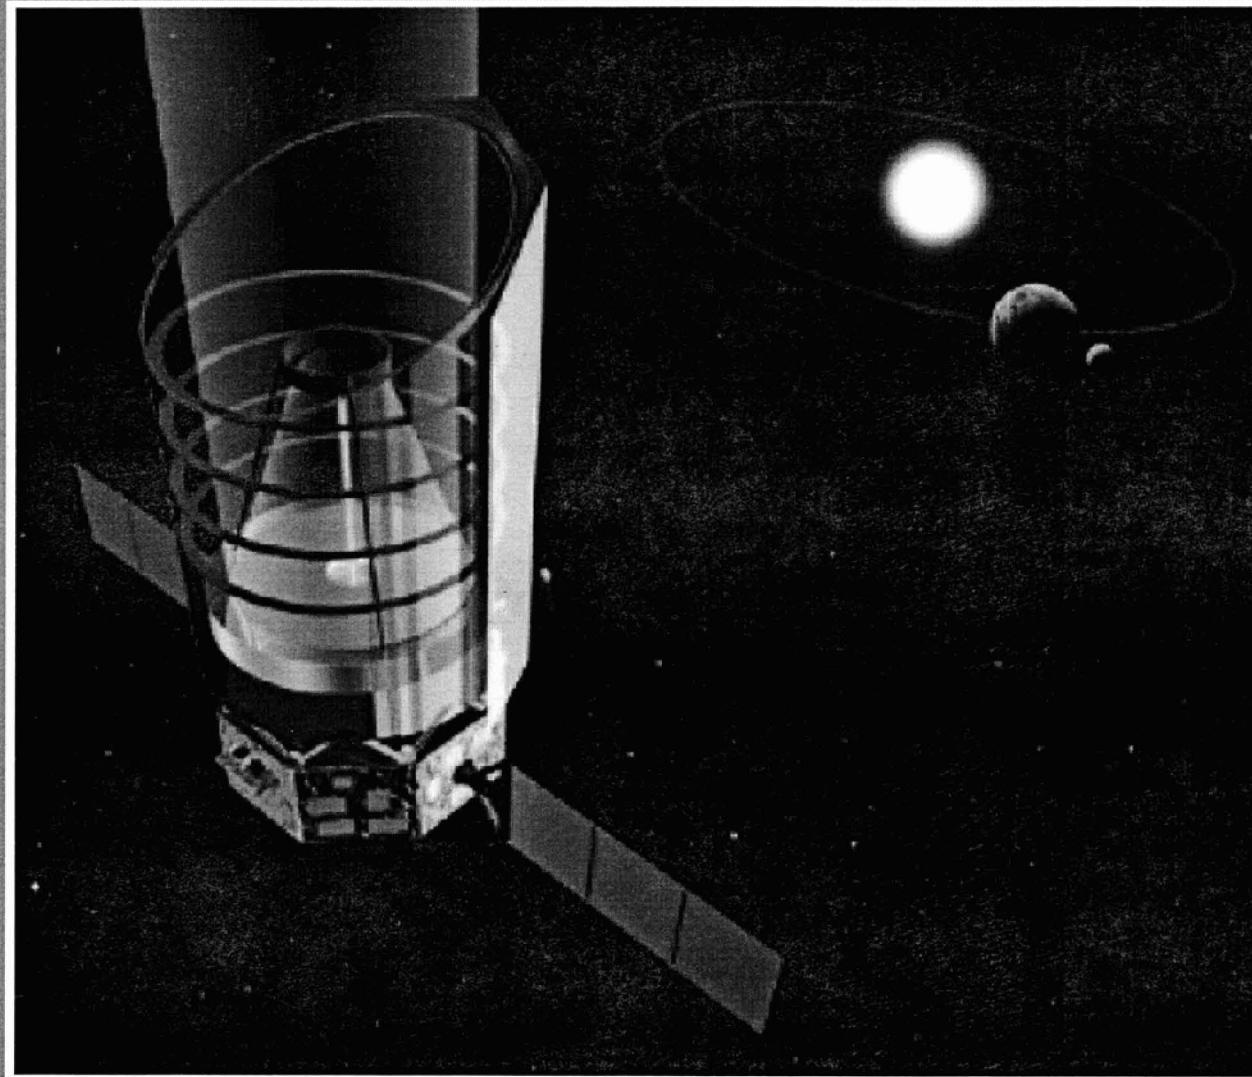

Platforms for BLISS: CALISTO

*Cryogenic Aperture Large IR Space Telescope
an Origins Probe concept -- PI Hal Yorke (JPL)*

- **Telescope** – 4 x 6 m primary, deployable secondary
 - Diffraction limited @ 40 μm
 - Off-axis design
- **Instrument** – Bridge wavelength gap between JWST and ALMA
 - Imaging photometry
 - Spectrograph
 - 20 – 300 μm @ R=3000
- **Delta II launch**
- **Earth-Sun L2 halo orbit**
 - Similar to Herschel, Planck, JWST
 - Stable thermal orbit; Sun/Earth side fixed
- **Mission lifetime**
 - Limited by component lifetime (cryocoolers, gyros)
 - 3 year baseline, possible extended mission

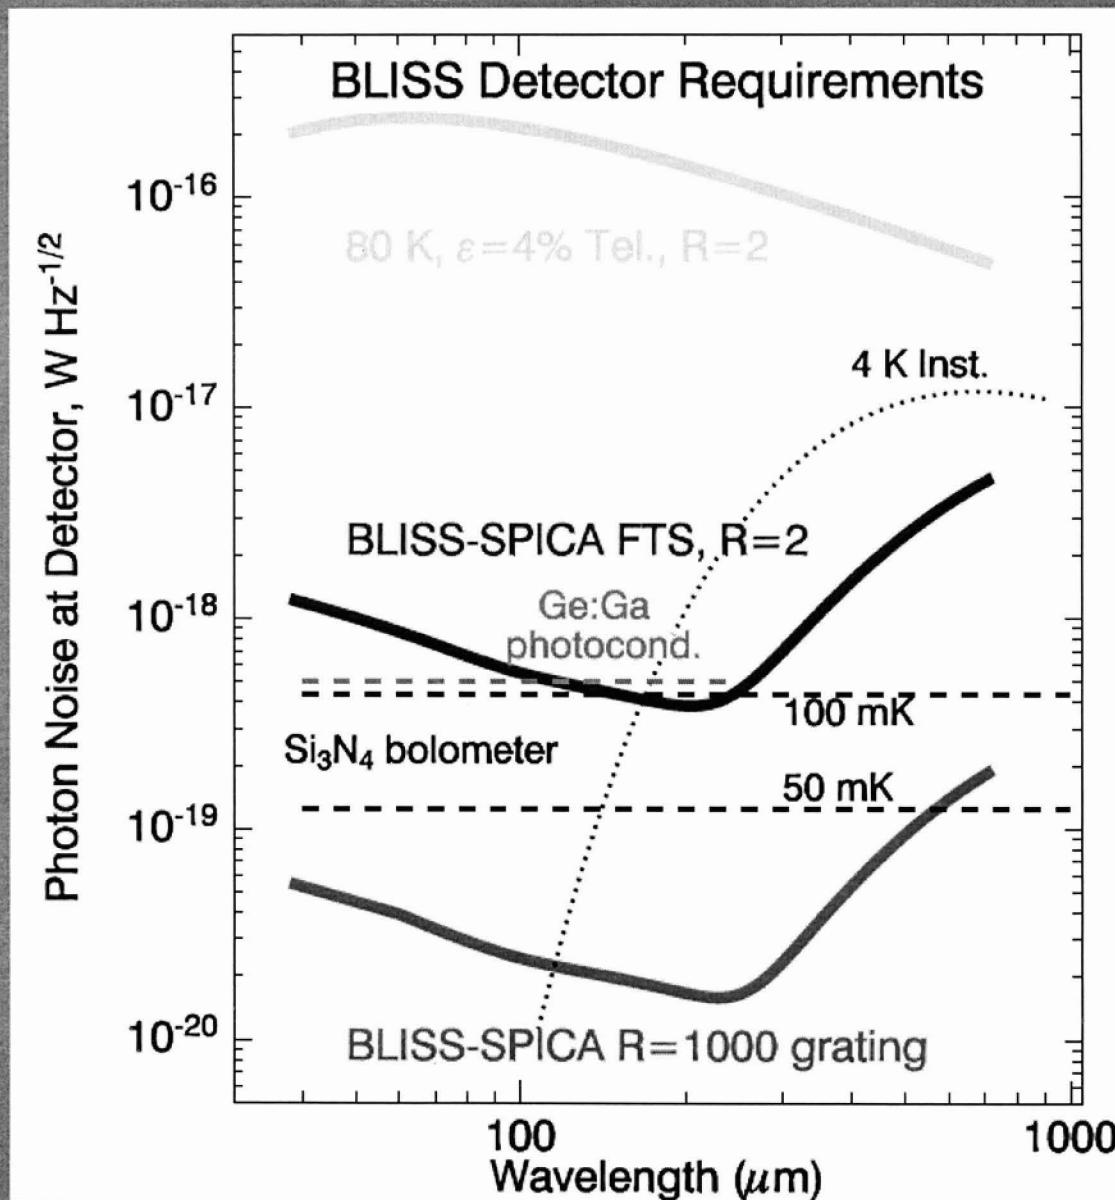

Platforms for BLISS: SPICA

*Space infrared
Telescope for
Cosmology
and Astrophysics
T. Nakagawa PI*

- **Size:** 3.5 m
- **Temperature:** 4.5 K
- **Cryogenics:**
Stirling + J-T closed cycle
- **Facility heat lift**
at 1.7 K: 10 mW
- **Orbit:** L2
- **Lifetime:** 5 years +
- **Launch:** ~2012

BLISS Detector Requirements

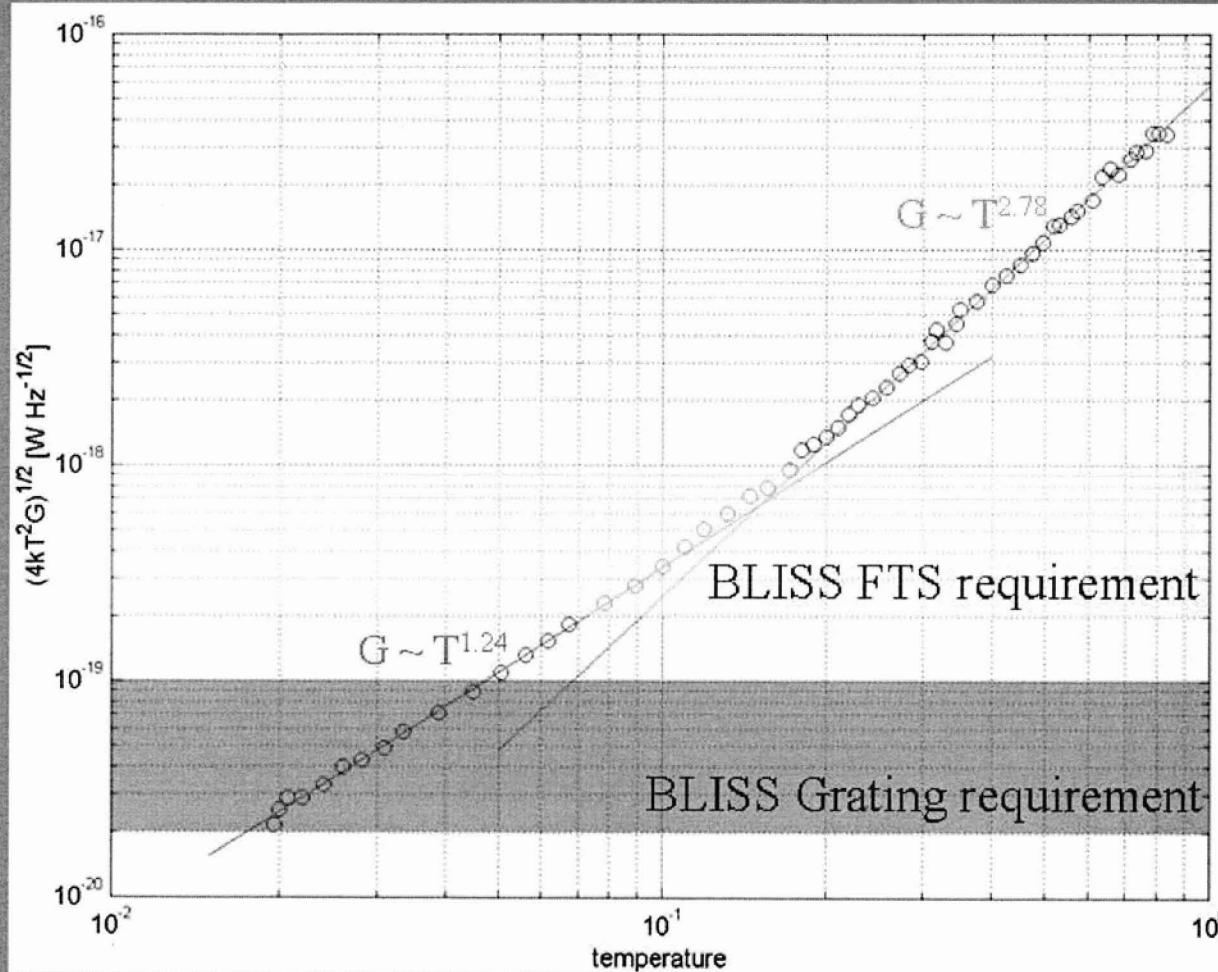

R=1000 is more challenging than any far-IR experiment thus far, no currently available devices for R=1000 spectroscopy.

BUT FTS background a good match to existing devices.

NB: Background from inside even 4 K instrument can become important.

Progress with SiN-suspended devices

Peter Day, JPL

Bolometers limited
by shot noise in
phonon transport:

$$\text{NEP} \sim (4kT^2G)^{1/2}$$

Measure $G(T)$, can
infer NEP.

3×10^{-20} at 30 mK

BLISS Architecture

Optimum sensitivity, large instantaneous band, reliability more important than spatial mapping, high spectral resolution

Grating spectrometer is the best choice

- 1st order → octave of instantaneous bandwidth
 - Good efficiency
- Fabry-Perot requires scanning for full spectral coverage
 - Scanning time prohibits spectral searching

Fourier transform spectrometer (FTS) couples the full band to a single detector

- Sensitivity penalty relative to monochromator for perfect detectors
 - Naturally accommodates 2-D spatial mapping
 - Flexible observing modes
- Best option for detector-noise limited operation*
- Heterodyne receivers subject to quantum noise
 - $\text{NEP}_{\text{QN}} \sim h\nu [\delta\nu]^{1/2}$ vs. $\text{NEP}_{\text{BG}} \sim h\nu [n(n+1) \delta\nu]^{1/2}$
 - Also offer small bandwidth:
 - 10 GHz backend at 1 THz gives $\nu / \Delta\nu \sim 100$

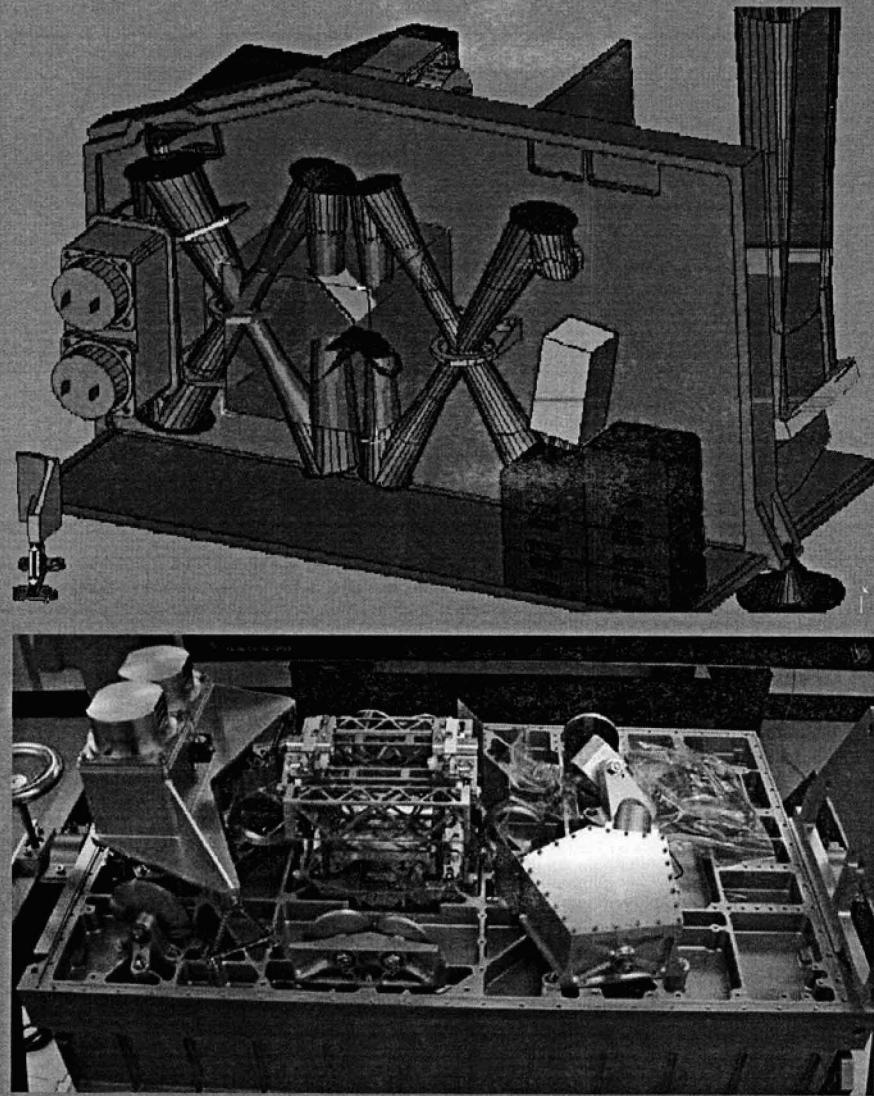

Imaging Fourier-Transform BLISS

Have flight heritage with Herschel
SPIRE (Swinyard, Griffin)
many problems solved
--> broadband beam splitter

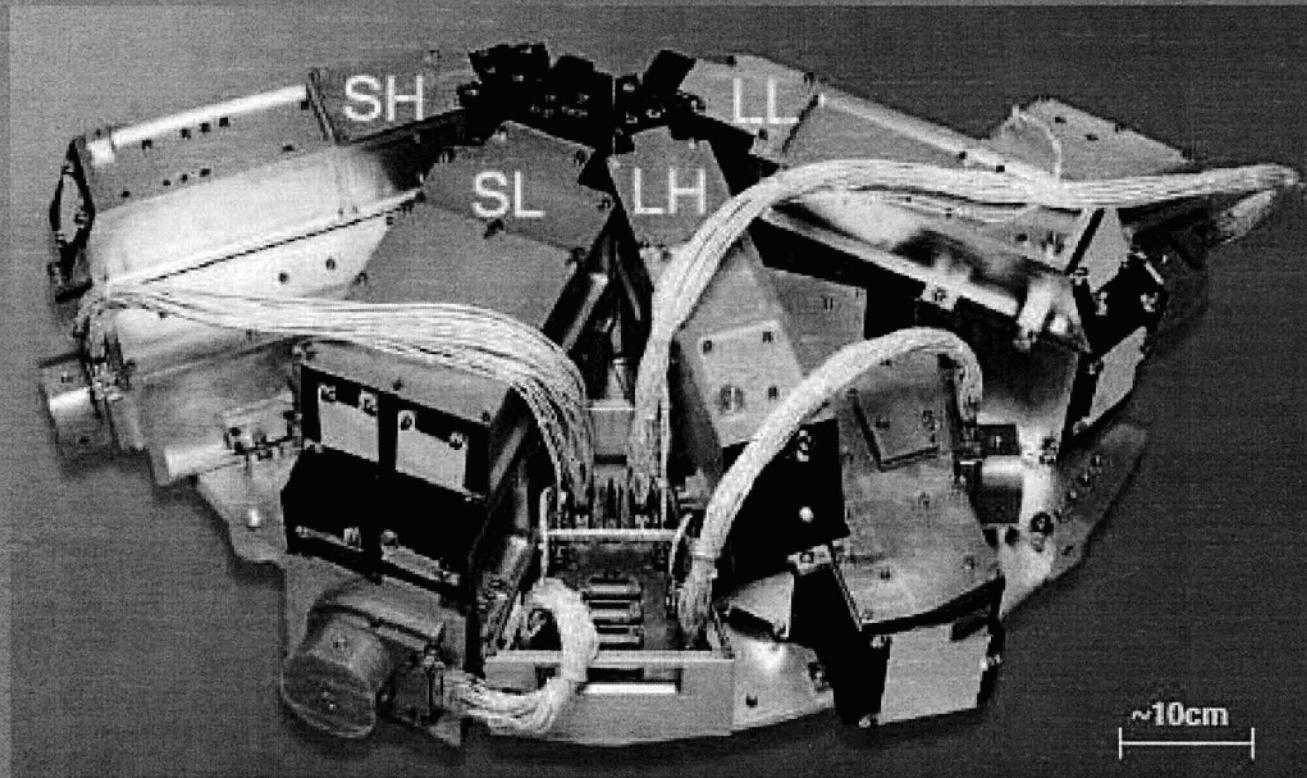

Instrument backgrounds must be
lower --> optics colder

Detector NEP are achievable with
today's devices

*Could start construction on a
sensitive far-IR FTS today!*

Broadband Grating Spectrometers

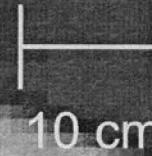

Spitzer IRS modules -- Houck, Roellig et al. 04

Spitzer IRS Hi-res modules are well-suited to broadband, point source spectroscopy.

R~600, multiple echelle orders sorted into a square array, no scanning required.

10--40 μm

IRS architecture cannot scale

Spitzer IRS Hi-res modules are well-suited to broadband, point source spectroscopy.

R~600, multiple echelle orders sorted into a square array, no scanning required.

50--200 μ m

Spitzer IRS modules -- Houck, Roellig

Instrument size an issue for long λ grating systems
Conventional broadband grating systems are huge when scaled to $\lambda \sim 100 \mu\text{m}$

SIRTF IRS Long-Hi module:
 $40 \times 15 \times 20 \text{ cm}$ for $R=600$ at $37 \mu\text{m}$.
→ For $200 \mu\text{m}$, this module would be over 2 meters in size.

→ Much larger than required by fundamental limit: $L = R \times \lambda$.

*SIRTF IRS long-high module--Roellig et al.
1999*

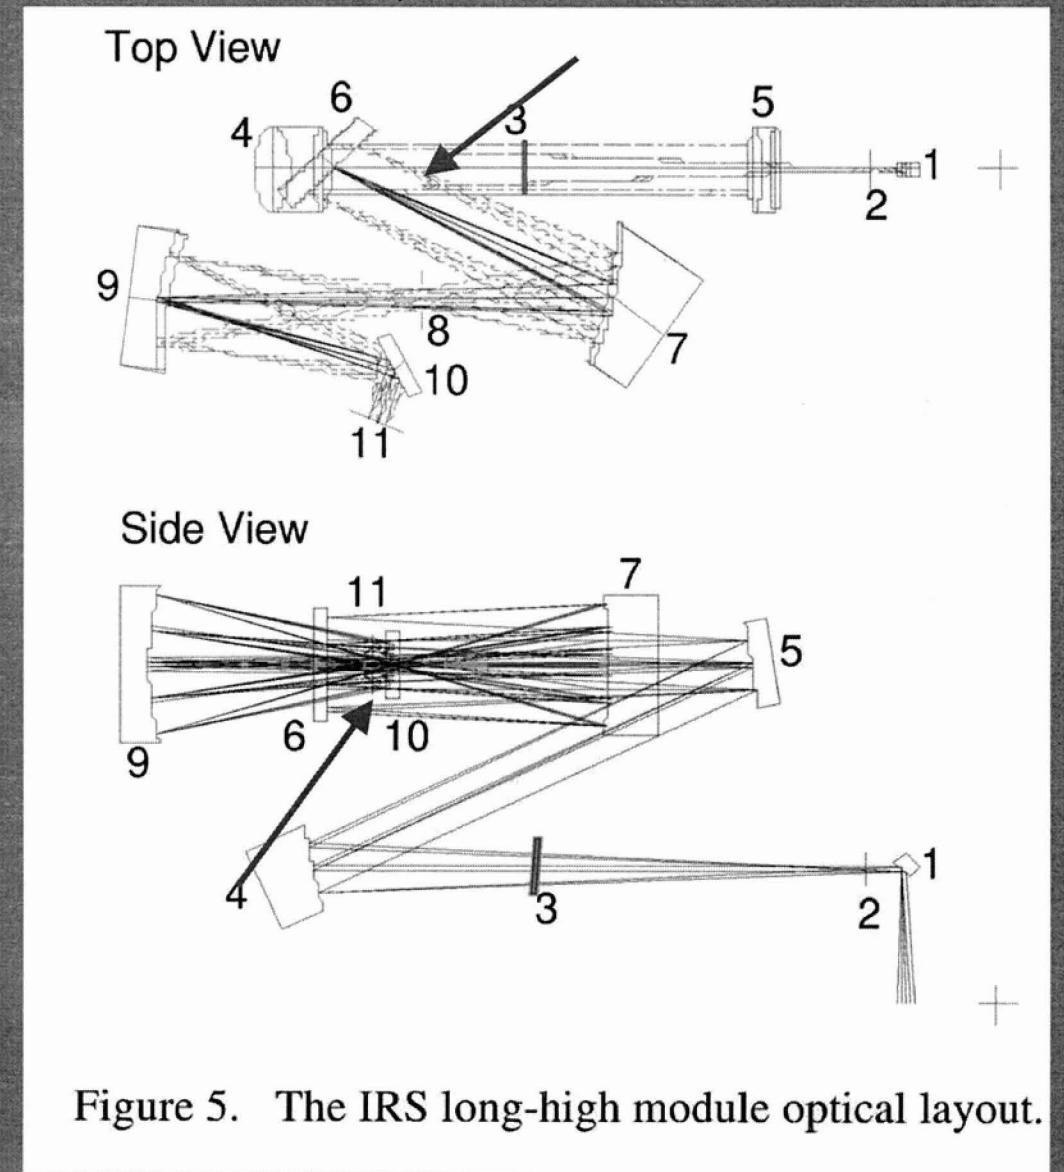

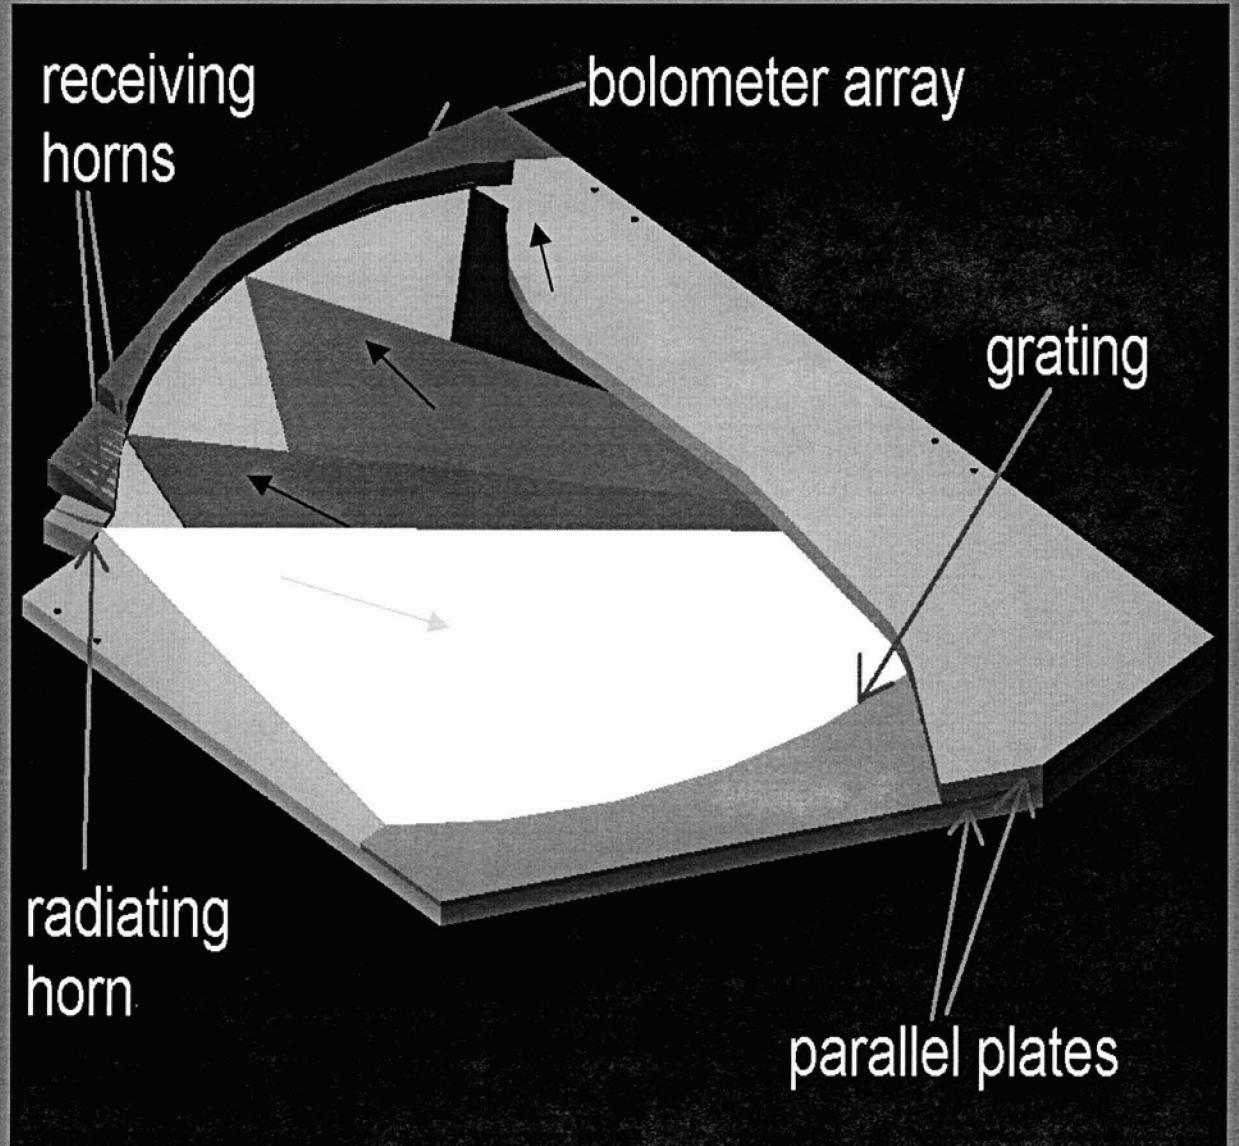

Figure 5. The IRS long-high module optical layout.

Solution: WaFIRS Spectrometer Module

curved grating in parallel plate waveguide

- Propagation confined in parallel-plate waveguide
 - 2-D Geometry
 - Stray light eliminated
- Curved grating diffracts and focuses
 - Efficient use of space
 - No additional optical elements

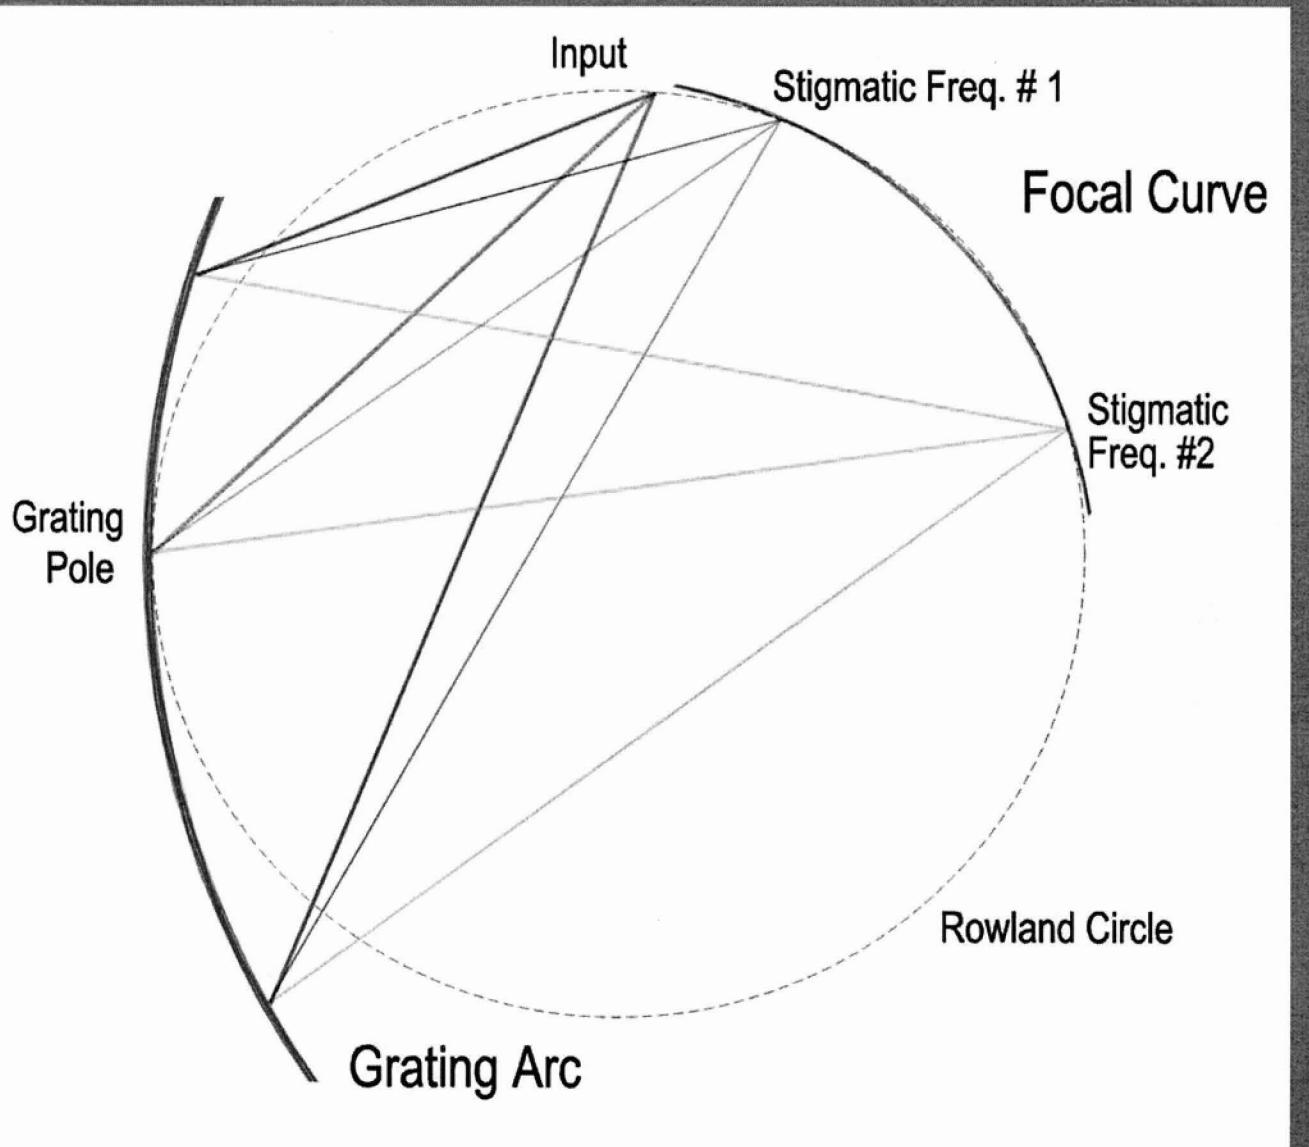

H.A. Rowland, 1883, Phil. Mag 16
K.A. McGreer, 1996, IEEE Phot. Tech. 8

Curved grating has stigmatic design

Each facet positioned to provide perfect performance at two frequencies

→ System is diffraction-limited over the full band.

Z-Spec is WaFIRS prototype for ground-based mm-wave spectroscopy

Z-Spec is multi-institutional collaboration:

Colorado: Glenn

JPL: Bradford, Bock, Nguyen, Dragovan

Caltech: Zmuidzinas

ISAS, Japan: Matsuura

CEA, Saclay: Duband

Cover 195-310 GHz window instantaneously with R=250-450

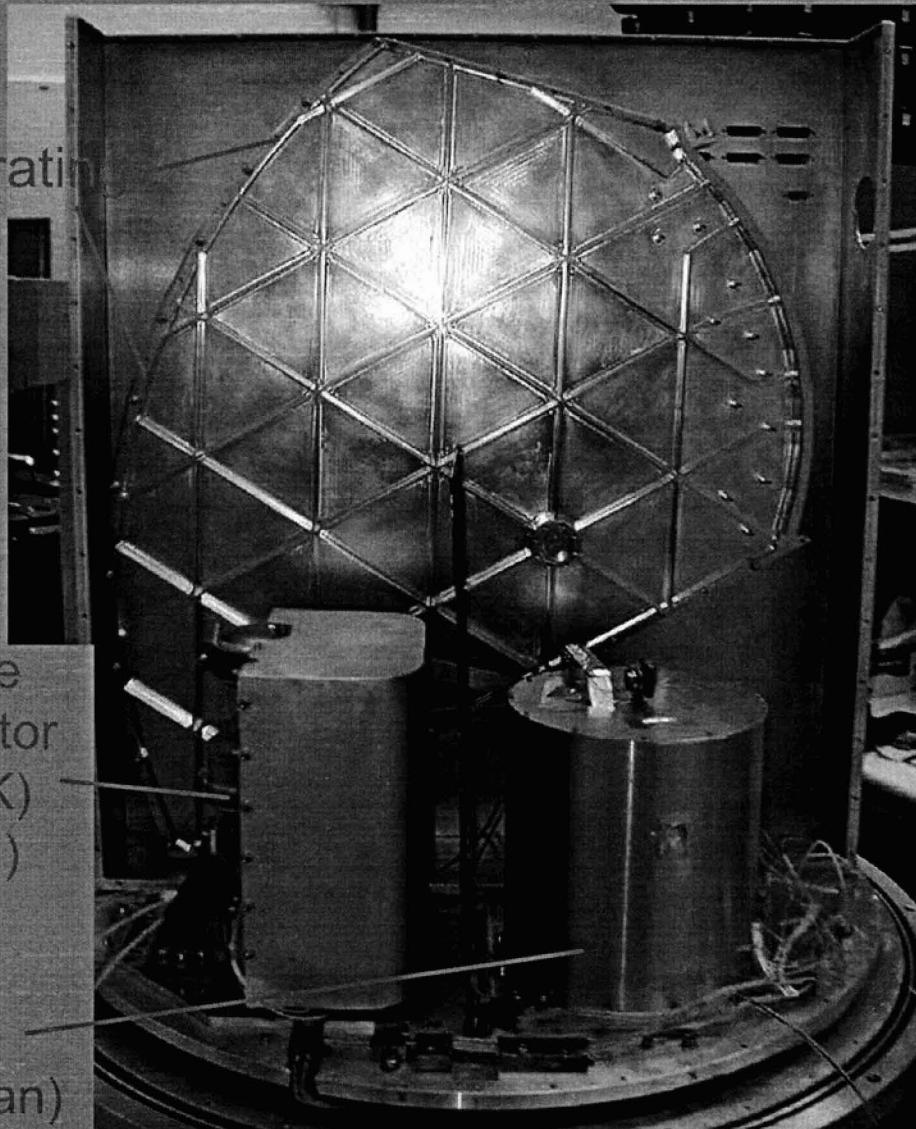

- > Measure redshifts with CO lines in high-z galaxies
- > CSO, IRAM, LMT

160 Si₃N₄ micromesh bolometers, BG limited on ground

- > Entire device cooled to < 0.1 K

Z-Spec is WaFIRS prototype for ground-based mm-wave spectroscopy

Grating

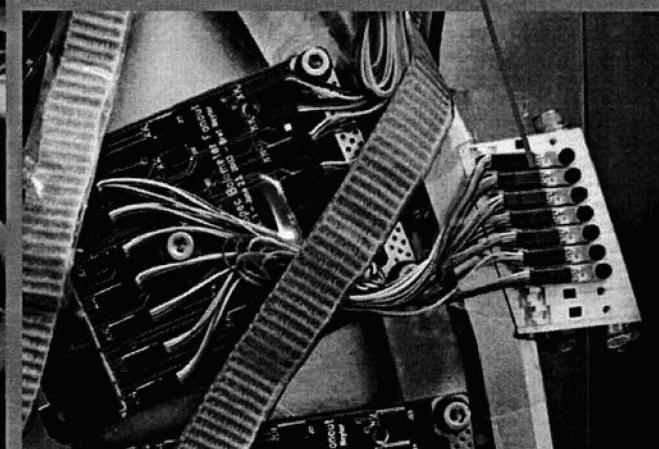

^3He - ^4He
refrigerator
(0.35 K)
(Duband)

ADR
(0.06 K)

Single-mode illuminating
feed and transformer

Multi-mode detector feeds

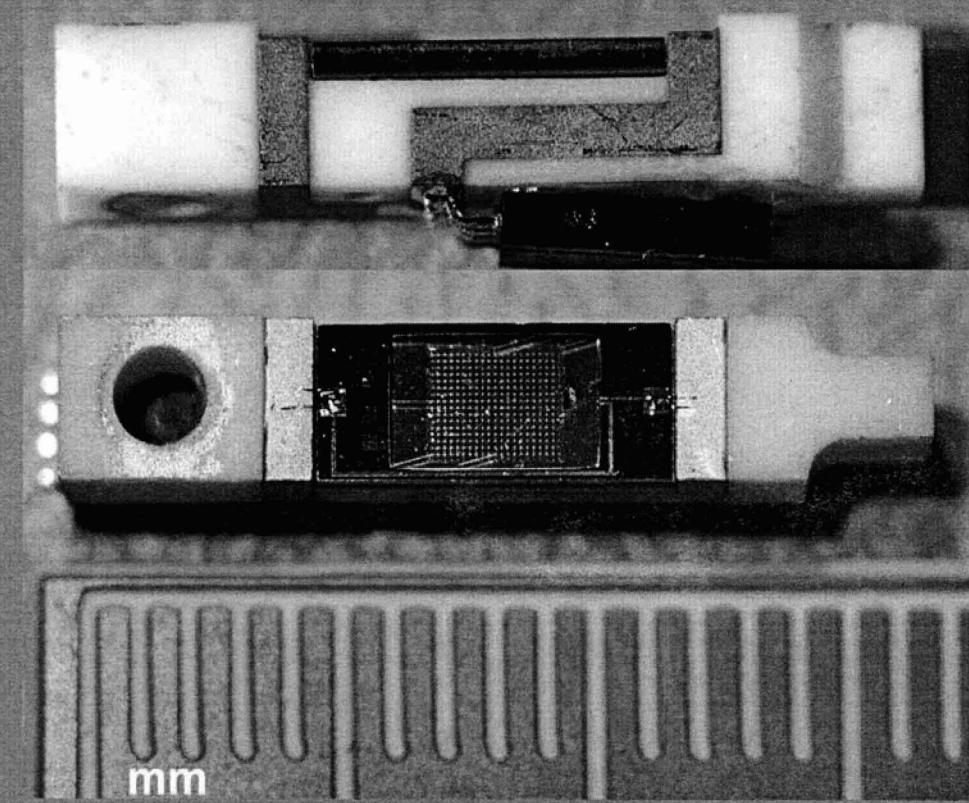

Z-Spec is WaFIRS prototype for ground-based mm-wave spectroscopy

See also Naylor poster, Jason Glenn

8 waveguide feed blocks --
each illuminates 20 bolometers

micromesh NTD-thermistor
bolometers, each individually
mounted.

Mm-wave WaFIRS prototype ought to scale to shorter wavelengths, higher R

Table 3. Scalability of WaFIRS Modules

Design Parameter	Z-Spec (built)	SPICA far-IR	SPICA far-IR
Wavelength	μm	970-1540	160-300
Medium		Vacuum	Vacuum
Detectors	#	160	500
Facets	#	480	4000
Resolving Power	$\lambda/\Delta\lambda$	250-400	1000-1600
Spacing	mm	2.5	0.6
Tolerance	μm	40	5
Length	mm	610	550
Efficiency		0.78-0.85	0.90-0.93

- 2-D geometry offers potential for stacking multiple modules in the focal plane.
- Dielectric immersion can further reduce size, mass.

Summary

- The bulk of the cosmic far-IR background light will soon be resolved into its individual sources with Spitzer, Astro-F, Herschel, and submm / mm ground-based cameras. The sources will be dusty galaxies at $z \sim 1-4$. Their physical conditions and processes in these galaxies are directly probed with moderate-resolution spectroscopy from $30 \mu\text{m}$ to 1 mm.
- The combination of large cold telescopes with sensitive direct detectors is now at hand, offering the potential for mid-far-IR spectroscopy at the background limit (BLISS). The capability will allow routine observations of even modest high-redshift galaxies in a variety of lines. SPICA and US probe-class missions are excellent candidates for operation within the decade, leading the way for SAFIR.
- An imaging Fourier-Transform system is a good match to present-day detector technology.
- The most efficient broadband instrument uses a grating spectrometer with $\text{NEP} \sim 10^{-20}$ detectors.
- Classical grating spectrometer architectures are prohibitively large for far-IR wavelengths, and new architectures such as WaFIRS are required.
